| <b>Description</b>    | <p>Use this message to download PPL tables that are subsequently used to create a PPL protocol.</p> <p>Before using this message, the host must first establish the table to be downloaded using the <i>PPL Table Initiate Download</i> message. The <i>PPL Table Download</i> message is then used to pass the table data to the CSP.</p> <p>If the table data exceeds the maximum length allowed for one message, you will have to use more than one of these messages. You must send them sequentially because the CSP maintains the offset into the table on successive commands.</p> |
| <b>Sent by</b>        | Host                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### SwitchKit Code C Structure

```
typedef struct {
 unsigned short ComponentID;
 UBYTE TableType;
 UBYTE TableID;
 UBYTE Data[249];
} XL_PPLTableDownload;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE DataSize;
 UBYTE ErrorType;
 UBYTE Data[250];
} XL_PPLTableDownloadAck;
```

### C++ Class

```
class XLC_PPLTableDownload : public XLC_OutboundMessage {
public:
 unsigned short GetComponentID() const;
 void setComponentID(unsigned short x);
 UBYTE getTableType() const;
 void setTableType(UBYTE x);
 UBYTE getTableID() const;
 void setTableID(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**C++ Class Response**

```

class XLC_PPLTableDownloadAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getDataSize() const;
 void setDataSize(UBYTE x);
 UBYTE getErrorType() const;
 void setErrorType(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};

```

**EXS API Hex Format**

### Primitive Table Format (0x01)

A Primitive Table is a set of primitives used in conjunction with a State/Event Table to create a PPL protocol. Each Primitive Table can contain up to 400 primitives. The Primitive Table is assigned to the protocol when the protocol is created with the *PPL Create* message.

The Primitive Table format is shown in the table below.

| Byte           | Field Description           | Definition                                  |
|----------------|-----------------------------|---------------------------------------------|
| Message Header |                             |                                             |
| 8, 9           | PPL Component ID (MSB, LSB) | See list of Component IDs in this document. |
| 10             | Table Type                  | 0x01 Primitive Table                        |
| 11             | Table ID                    | Assigned by host.                           |
| Table Data     |                             |                                             |

|                                                |                                   |                                                                                                                                                                                                                              |
|------------------------------------------------|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12, 13                                         | Data[0,1] Primitive ID (MSB, LSB) | Identifies each primitive in the primitive table. Each primitive in the table must be unique, and in the range from 0 to 199. The primitives in the table must be ordered lowest number to highest (numbers may be skipped). |
| 14                                             | Data[2] Number of AFs             | The number of AFs used to create the primitive (1 to 10).                                                                                                                                                                    |
| 15, 16                                         | Data[3,4] AF: ID (MSB, LSB)       | The AF ID specifies the predefined function to be invoked (in the range supplied by Cantata ).                                                                                                                               |
| 17, 18                                         | Data[5,6] Arg 1 Value (MSB, LSB)  | The first argument value to pass to the AF.                                                                                                                                                                                  |
| 19, 20                                         | Data[7,8] Arg 2 Value (MSB, LSB)  | The second argument value to pass to the AF.                                                                                                                                                                                 |
| Repeat Data[3-8] for each AF in the primitive. |                                   |                                                                                                                                                                                                                              |
| :                                              | Checksum                          |                                                                                                                                                                                                                              |

### Basic State/Event Table Format (0x02)

A Basic State/Event table is a group of valid events that pertain to a given state, the primitives that get invoked upon the occurrence the event, and the next state to transition into in response to the event(s). State/event tables allow for up to 100 states and up to 20 events per state. The Primitive Table is assigned to the protocol when the protocol is created with the *PPL Create* message.

The Basic State/Event Table format is shown in the table below.

| Byte           | Field Description                          | Definition                                                                                                                                                                                 |
|----------------|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Message Header |                                            |                                                                                                                                                                                            |
| 8, 9           | PPL Component ID (MSB, LSB)                | See list of Component IDs in this document.                                                                                                                                                |
| 10             | Table Type                                 | 0x02 Basic State/Event Table                                                                                                                                                               |
| 11             | Table ID                                   | Assigned by host                                                                                                                                                                           |
| Table Data     |                                            |                                                                                                                                                                                            |
| 12             | Data[0] Table Data<br>Initial State Number | Identifies the current state that the protocol is in. States must be specified in order from 1 to 199. State numbers can be skipped. The initial State Type is assumed to be Normal.       |
| 13             | Data[1] Number of Events                   | The number of valid events accepted by the state. Each state can accept up to 120 events. For best performance, events most likely to occur should be placed at the beginning of the list. |
| 14, 15         | Data[2, 3] Event 1 # (MSB, LSB)            | See the for event data.                                                                                                                                                                    |
| 16, 17         | Data[4, 5] Event Data 1 Value (MSB, LSB)   |                                                                                                                                                                                            |
| 18, 19         | Data[6, 7] Event Data 2 Value (MSB, LSB)   |                                                                                                                                                                                            |
| 20, 21         | Data[8, 9] Primitive ID (MSB, LSB)         | The primitive invoked when the specified event occurs based on the Primitive Table associated with the event.                                                                              |
| 22             | Data[10] Next State Number                 | The state that the protocol should enter in response to the indicated event(s).                                                                                                            |

|                                                             |                          |                                   |
|-------------------------------------------------------------|--------------------------|-----------------------------------|
| 23                                                          | Data[11] Next State Type | 0x01 Normal/Wait<br>0x02 Internal |
| Repeat Data[2-11] for each event associated with the state. |                          |                                   |
| :                                                           | Checksum                 |                                   |

**Route Table (0x03)** The Route Table format is shown in the table below.

| Byte           | Field Description                                                      | Definition                                                                                                                                                                                                                                                                                                                                                             |

| :              | Checksum                                                               |                                                                                                                                                                                                                                                                                                                                                                        |

**Route Criteria Type entries**    0x0007 Incoming Span/Channel, Single/Range  
                                          0x0009 Terminating Span/Channel, Single/Range

0x0010 Incoming Resource Group, Single/Range  
 0x0015 Terminating Resource Group, Single/Range  
 0x0065 Physical VoIP Channel  
 0x0071 Virtual VoIP Channel  
 0x03E9 User-defined

**NOTE:** See Notes 1, 2 and 3 below to configure the following Route Criteria Type entries.

0x2710 Universal Protocol Data, Single/Range  
 0x2717 Called Party Number, Single/Range  
 0x2718 Calling Party Number, Single/Range  
 0x2792 Source IP Address, Single/Range  
 0x2794 Destination IP Address, Single/Range  
 0x27B0 RTP Payload Type, Single/Range  
 0x27B4 IP Address Criteria, Single/Range  
 0x2919 NPDI SIP to Username, Single/Range  
 0x291A NPDI SIP to Hostname, Single/Range  
 0x2919 NPDI SIP from Username, Single/Range  
 0x291A NPDI SIP from Hostname, Single/Range  
 0x2A0E Media Connection Address, Single/Range

### Notes

1. The second data format field that occurs after the length can have the following values:
  - 0x01 - Data in Raw Hex Bytes
  - 0x02 - ASCII Characters
  - 0x03 - BCD (all digit-based routes are BCD)
  - 0x04 - Decimal

2. The length of the this field is variable. It is equal to the Criteria Length minus the length of the Criteria Header information (for example, all fields after the length and not including the digits and mask fields) divided by the number of digits and mask fields included.

Below is an example of how the Single bit in the Route Property Mask is set (see field 15 in Route Table (0x03) above).

To compute the Length of Field which is equal to 7, do the following:

Criteria Length (20) subtract (-) Length of Criteria Header (6) and divide (/) by number of Digit and Mask fields (2)

```
2a 0e \' Media Connection Criteria Type
03 \' Criteria Data Format: BCD
00 14 \' Length
03 \'Criteria Data Format: BCD
63 \' Offset
```

00 00 00 00 \ ' Reserved - set to 0x00 0x00 0x00 0x00

04 05 05 06 06 07 08 \ ' Digits string

0f 0f 0f 0f 0f 0f \ ' Mask

Below is an example of how the Range bit in the Route Property Mask is set (see field 15 in Route Table (0x03) above).

To compute the Length of Field which is equal to 1, do the following:

Criteria Length (9) subtract (-) Length of Criteria Header (6) and divide (/) by number of Digit and Mask fields (3)

2a 0e \ ' Media Connection Criteria Type

01 \ ' Criteria Data Format

00 09 \ ' Length

04 \ ' Criteria Data Format: Decimal

2c \ ' Offset

00 00 00 00 \ ' Reserved

0a \ ' From digits

cd \ ' To digits

ff \ ' Mask

3. The Offset field represents the number of channels to offset outgoing channel from incoming channel.

### Extended State/Event Table Format (0x07)

An Extended State/Event table is a group of valid events that pertain to a given state, the primitives that get invoked upon the occurrence the event, and the next state to transition into in response to the event(s). State/event tables allow for up to 100 states and up to 20 events per state. The Primitive Table is assigned to the protocol when the protocol is created with the *PPL Create* message.

The Extended State/Event Table format is shown in the table below.

| Byte           | Field Description                        | Definition                                                                                                                                                                                                                                                                 |
|----------------|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Message Header |                                          |                                                                                                                                                                                                                                                                            |
| 8, 9           | PPL Component ID (MSB, LSB)              | See list of Component IDs in this document.                                                                                                                                                                                                                                |

| 11             | Table ID                                 | Assigned by host                                                                                                                                                                                                                                                           |
| Table Data     |                                          |                                                                                                                                                                                                                                                                            |
| 12             | Data[0,1] Initial State Number           | Identifies the current state that the protocol is in. States must be specified in order from 1 to 199. State numbers can be skipped. The initial State Type is assumed to be Normal.                                                                                       |
| 13             | Data[2] Number of Events                 | The number of valid events accepted by the state. Each state can accept up to 120 events. For best performance, events most likely to occur should be placed at the beginning of the list.                                                                                 |
| 14, 15         | Data[3,4] Event 1 # (MSB, LSB)           | Bytes 14 and 15 are external processing events, such as, Alerting or Answer; or internal decision events. Bytes 16-19 are arguments that relate to events such as, filter timer IDs for line signaling events. See the <i>API Developer's Guide: PPL</i> for more details. |
| 16, 17         | Data[5, 6] Event Data 1 Value (MSB, LSB) |                                                                                                                                                                                                                                                                            |
| 18, 19         | Data[7, 8] Event Data 2 Value (MSB, LSB) |                                                                                                                                                                                                                                                                            |
| 20, 21         | Data[9, 10] Primitive ID (MSB, LSB)      | The primitive invoked when the specified event occurs based on the Primitive Table associated with the event.                                                                                                                                                              |
| 22             | Data[11, 12] Next State Number           | The state that the protocol should enter in response to the indicated event(s).                                                                                                                                                                                            |
| 23             | Data[13] Next State Type                 | 0x01 Normal/Wait<br>0x02 Internal                                                                                                                                                                                                                                          |

|                                                             |          |  |
|-------------------------------------------------------------|----------|--|
| Repeat Data[2-13] for each event associated with the state. |          |  |

| <b>Description</b>    | <p>This message initiates a report from the CSP on the custom protocols (non-default) that have been downloaded to a PPL component. There are two methods.</p> <p>The first indicates every table downloaded to a particular PPL component and its associated protocols, if any. This is Sent by setting the Entity field to 0x00 (All Tables).</p> <p>The second indicates the name of a particular entity (table or protocol). This is initiated by setting the Entity field to either 0x01 (Primitive Table), 0x02 (State/Event Table), or 0x03 (Protocol), and specifying the ID in the Entity ID field.</p> |
| <b>Sent by</b>        | Host                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### SwitchKit Code C Structure

```
typedef struct {
 unsigned short ComponentID;
 UBYTE Entity;
 UBYTE EntityID;
} XL_PPLProtocolQuery;
```

### C Structure Response

```

**Examples****Assumptions**

- Component: 0x12
- Downloaded Protocols  
02 cpc\_CPG\_T7
- Primitive Tables  
02 isup\_cpc\_itu\_ppl\_pr
- State Event Tables  
02 isup\_cpc\_itu\_ppl\_st

**Query All Tables**Message

To query all tables, you would send the message as shown below, with the following values:

- Component ID: **00 12**
- Entity: All Tables (**00**)
- Entity ID: **00**

H->X

[00 09 00 df 00 00 ff 00 12 00 00]

Response

The CSP returns the following bytes indicating that component 12 has 2 tables:

- Primitive Table 02 (Protocol 2)
- State Event Table 02 (Protocol 2)

X->H

[00 12 00 df 00 00 01 00 10 00 12 00 00 **02 01 02 02 02 02** 02]

### Query Primitive Table

#### Message

To retrieve the name of Primitive Table 2, you would send the following bytes:

- Entity **01** (Primitive Table)
- Entity ID **02**

H->X

[00 09 00 df 00 00 ff 00 12 **01 02**]

#### Response

The CSP responds with a string of ASCII characters indicating the protocol name: isup\_cpc\_itu\_ppl\_pr

X->H

[00 1f 00 df 00 00 01 00 10 00 12 01 02 **69 73 75 70 5f 63** 70 63 5f 69 74 75 5f 70 70 6c 5f 70 72 00]

Query Entities 0x02 (State/Event Table), 0x03 (Protocol), and 0x07 (Extended State/Event Table) would return similar results.

## PPL Table Download Initiate 0x00D5

# PPLTool

---

|                    |                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Type</b>        | SwitchKit API message                                                                                                                                       |
| <b>Purpose</b>     | Use the PPLTool message to send either a hex format configuration (*.cfg) or a *.rep file (generated from Cantata's technical support) to a specified node. |
| <b>Description</b> | This message downloads <u>either</u> a *.rep file or a *.cfg file (but not both) to the switch.                                                             |
| <b>Sent by</b>     | SwitchManager                                                                                                                                               |
| <b>Arguments</b>   | The following table shows the user modifiable arguments of this message:                                                                                    |

| Argument | Description                                                                                          |
|----------|------------------------------------------------------------------------------------------------------|
| Node     | The node ID the file is destined for.                                                                |
| cfgFile  | The *.cfg filename of the file to parse and send. The maximum size of the cfgFile name is 160 bytes. |
| repFile  | The *.rep filename of the file to parse and send.                                                    |

**Configuration** To download a PPL rep file:

```
pplTool(
 Node = integer,
 repFile = quoted string);
```

To download a configuration file:

```
pplTool(
 Node = integer,
 cfgFile = quoted string);
```

**C Structure**

```
typedef struct {
 char RepFile[100];
 char CfgFile[100];
} SK_PPLTool;
```

**C++ Class**

```
class SK_PPLTool : public SKC_DummyMessage {
public:
 const char *getRepFile() const;
 void setRepFile(const char *x);
 const char *getCfgFile() const;
 void setCfgFile(const char *x);
};
```

# PPL Timer Configure 0x00CF

SwitchKit Name

PPLTimerConfig

Type

EXS API and SwitchKit API message

Description

This message allows the host to configure PPL timers.

The 100 generic timers are used as defined by the protocol tables. The protocol designer must specify which timers are used, and how. This message allows the timers to be adjusted without having to modify the PPL State/Event or Primitive Tables.

NOTE:

This message does not support the older ST1LC line cards. The correct message to use for these older line cards is the *Filter/Timer Configure* message (0x12).

Sent by

Host

Overview of message

The following table provides an overview of this message. The table following it, provides the detail for each byte.

| <b>Description</b>    | <p>This message allows the host to configure transmit line signaling on channels with a trunk type of PPL.</p> <p>The idle signal is used by the internal out-of-service protocol to transmit idle code when transitioning to the primary protocol. The out-of-service signal is used when transitioning to the out-of-service protocol.</p> |
| <b>Sent by</b>        | Host                                                                                                                                                                                                                                                                                                                                         |

### SwitchKit Code Configuration

```
PPLTransmitSignalConfig (
 Node = integer,
 StartSpan = integer,
 StartChannel = integer,
 EndSpan = integer,
 Range = StartSpan:StartChan - EndSpan:EndChan,
 EndChannel = integer,
 ComponentID = integer,
 ProtocolSignalingState = integer,
 SignalingBits = integer);
```

### C Structure

```
typedef struct {
 unsigned short StartSpan;
 UBYTE StartChannel;
 unsigned short EndSpan;
 UBYTE EndChannel;
 unsigned short ComponentID;
 UBYTE ProtocolSignalingState;
 UBYTE SignalingBits;
} XL_PPLTransmitSignalConfig;
```

### C++ Class

```
class XLC_PPLTransmitSignalConfig : public
 XLC_OutboundMessage {
public:
 unsigned short getStartSpan() const;
 void setStartSpan(unsigned short x);
 UBYTE getStartChannel() const;
 void setStartChannel(UBYTE x);
 unsigned short getEndSpan() const;
 void setEndSpan(unsigned short x);
 UBYTE getEndChannel() const;
 void setEndChannel(UBYTE x);
 unsigned short getComponentID() const;
 void setComponentID(unsigned short x);
```

```

UBYTE getProtocolSignalingState() const;
void setProtocolSignalingState(UBYTE x);
UBYTE getSignalingBits() const;
void setSignalingBits(UBYTE x);
};

```

| <b>Description</b>                                       | <p>This message is used to download one software key. Regardless of how a software or hardware module has been locked, you unlock all functionality with this message.</p> <p>This message provides the mechanism for a host application to send the software feature or hardware upgrade license codes to the CSP. In a multi-node system, any node will accept and recognize these software feature licenses.</p> <p><b>NOTES:</b> For <i>SwitchKit</i>, when resetting a card such as, a T_ONE, E-ONE or J-ONE, a <i>ProductLicenseDownload</i> message is sent by SwitchManager so that the licensed hardware is available after a card reset. If the licensed card is permanently removed and the corresponding <i>ProductLicenseDownload</i> is not removed from the configuration, then any subsequent resets of matching card types will cause the <i>ProductLicenseDownload</i> to be NACKed.</p> |

| <b>Description</b>    | This message is used to provide information about product licenses that are currently installed on the CSP. |
| <b>Sent by</b>        | Host                                                                                                        |

**SwitchKit Code    C Structure**

```
typedef struct {
 } XL_ProductLicenseQuery;
```

**C Structure Response**

```
typedef struct {
 unsigned short Status;
 UBYTE NumLicenses;
 UBYTE Data[250];
 } XL_ProductLicenseQueryAck;
```

**C++ Class**

```
class XLC_ProductLicenseQuery : public
 XLC_OutboundMessage {
public:
 };
```

**C++ Class Response**

```
class XLC_ProductLicenseQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getNumLicenses() const;
 void setNumLicenses(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
 };
```

**EXS API Hex Format**

### Memory Field Information

The memory is reported in 32-bit words because that is the smallest memory storage unit. This means that a RAN six bytes long uses 2 words of memory for storing the RAN data.

Both File System revisions 0 and 1 use 16 words of memory for header information for each RAN stored.

File System revision 0 removes 16 words for each of the 2048 RANs (32768 words total) that could be stored on the VRAS SIMM from the available

memory. So the total Available Memory for File System revision 0 is 0x5F8000. The Used Memory field counts only the memory words used for the RAN data, not the 16 words used for the RAN header.

File System revision 1 does not know the maximum number of RANs that may be stored on the VRAS SIMM, so the 16 words of header information for each RAN stored is added to the Used Memory for each RAN. Thus the total Available Memory for File System revision 1 is 0x600000. The deleted memory in the Defragmentation Level field also includes the 16 words for each deleted RAN.

## Recorded Announcement File System Convert 0x0118

| <b>Description</b>    | <p>This message converts the file system used by the VRAS SIMM's Flash memory on the DSP-ONE card to the file system specified in the File System field. The VRAS SIMM must first be taken out of service with the <i>Service State Configure</i> message.</p> <p>The host must wait for an <i>Alarm</i> message of “<i>Recorded Announcement File System Convert Success</i>” before bringing the VRAS SIMM in service. It may take up to five minutes for the alarm to be sent. If the conversion fails, the host receives an <i>Alarm</i> message of “<i>Recorded Announcement File System Convert Failure</i>” and the host should take action appropriate to the failure reason. The failure reason is in the Failure Code field of the <i>Alarm</i> message.</p> |
| <b>Sent by</b>        | Host                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Type</b>           | EXS API and SwitchKit API message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b>    | <p>This message deletes a single Recorded Announcement (RAN), provided that the VRAS SIMM's Flash File System has been upgraded to revision 1 (0x0001). For example, deleting RAN ID 0x0001 on VRAS SIMM 0x02, Slot 0x00 deletes any instance of RAN ID 0x0001 stored on the DSP-ONE card in Slot 0x00, SIMM 0x02. But all other instances of RAN ID 0x0001 stored on a different DSP-ONE card, or on a different VRAS SIMM on the same card, remain unchanged.</p> <p>This message can also be used just as the older message <i>Recorded Announcement Delete</i> (0x54) was used--to delete the VRA SIMM's entire Flash memory.</p> <p>The host should wait for an <i>Alarm</i> message of "Single RAN Deleted on SIMM" or "VRAS Erase Complete" before performing another deletion or download of a RAN. This message may be sent to an In Service or Out of Service VRAS SIMM.</p> <p>This message provides the following wildcards:</p> <ul style="list-style-type: none"><li>• Set the RAN ID field to 0xFFFF to delete all RANs on a Slot and VRAS SIMM (erase the VRAS SIMM's entire Flash memory). You <b>must</b> set the RAN ID to 0xFFFF if you are using the MFDSP card or you are using the DSP-ONE card with the older Flash File System, revision 0 (0x0000). When the RAN ID is 0xFFFF, a forced deletion is always performed (even currently-playing RANs are deleted).</li><li>• Set the VRAS SIMM field of the AIB to 0xFF to delete all instances of a RAN on all VRAS SIMMs.</li><li>• Set the Slot field of the AIB to 0xFF to delete all instances of a RAN on all slots.</li></ul> <p>You can combine the wildcards. For example, combining RAN ID 0xFFFF, VRAS SIMM 0xFF, and Slot 0xFF deletes <b>all</b> RANs stored on <b>all</b> VRAS SIMMs on <b>all</b> of the DSP cards (slots) in the chassis.</p> <p>The Forced Flag field indicates whether the host deletes the RAN forcefully or gracefully. A forced RAN deletion cancels even currently-playing instances of that RAN. The forced deletion also cancels the playing of a RAN chain that needs the RAN ID on the DSP-ONE card. When the RAN ID is the wildcard (0xFFFF) a forced deletion is always performed.</p> <p>A graceful RAN deletion is NACKed (and the RAN is not deleted) if the RAN is currently playing in Barge In mode, or if the RAN is needed for a current RAN chain or for a queued play request. If the RAN is currently playing, it is deleted only after it has finished playing. The graceful deletion is for single RAN IDs only.</p> |

| <b>Description</b>    | <p>This message recovers unused memory in the file system used by the VRAS SIMM's Flash memory on the DSP-ONE card. It is used after single Recorded Announcements (RANs) have been marked for deletion using the <i>Recorded Announcement Single Delete</i> (0x0117) message. The VRAS SIMM must first be taken out of service with the <i>Service State Configure</i> message. The host should wait for an <i>Alarm</i> message of "Recorded Announcement Defragment Complete" before bringing the VRAS SIMM in service. If defragmentation fails, the host receives an <i>Alarm</i> message of "Recorded Announcement File Defragmentation Failure" and the host should take action appropriate to the failure reason. The failure reason is in the Failure Code field of the <i>Alarm</i> message.</p> |
| <b>Sent by</b>        | Host                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b>          | <p>Use this message to connect a channel to one or a series of downloaded voice recorded announcements (RANs).</p> <p><b>NOTE:</b> You can use this message for the DSP Series 2 card, but only for RAN IDs below 4096. In CSPs using the DSP Series 2 card with the DSP-ONE card, the Matrix Controller examines the announcement ID(s) and determines if there are any DSP-ONE cards that can play the entire list of announcements. If there is no DSP-ONE card that can do this, the request is passed to the DSP Series 2 card. Because of this, the DSP Series 2 card must either have all the same announcements loaded onto it as all the DSP-ONEs via TFTP, or all the announcements must be accessible via NFS.</p> |

| <b>Description</b>    | This message deletes <i><b>all</b></i> announcements stored on a VRAS SIMM. Deletion of a SIMM takes approximately 30 seconds. The host should wait for an <i>Alarm</i> message of “VRAS Erase Complete” before downloading a new announcement to a SIMM.                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Recorded Announcement Download Initiate 0x0052

---

**SwitchKit Name** RecAnnDownloadInit

**Type** EXS API and SwitchKit API message

**Description** This is the first message sent by the host to initiate the downloading of a recorded announcement to a VRAS SIMM. If multiple SIMMs are to have the same announcement, each SIMM must be downloaded separately. If you try to use this message for the DSP Series 2 card, the Matrix Controller Series 3 card NACKs it.

### For SwitchKit

This message downloads a voice file to a VRAS board on the CSP. The format and encoding correspond to the arguments of the RecAnnDownloadInitiate message. The slot and SIMM must refer to a valid VRAS SIMM, and the ID is used to reference this prompt from future messages. If the voice file is already present on the SIMM, the SwitchManager bypasses the downloading. If there is another voice file with that ID already on the SIMM, then the configuration fails. The VRAS SIMM must be cleared with a RecAnnDelete before the new voice file is downloaded.

**Sent by** Host (SwitchManager for SwitchKit)

**Example Message (Socket Log Output for SwitchKit)** See *Recorded Announcement Download 0x0053* for the socket log output/example of the *Recorded Announcement Download Initiate* message and a *Recorded Announcement Download* message together.

**SwitchKit Code** **Configuration**

```
RecordedAnnouncement(
 file = quoted string,
 slot = integer,
 SIMM = integer,
 id = integer,
 format = integer,
 encoding = integer
);
```

### C Structure

```
typedef struct {
 UBYTE Slot;
 UBYTE SIMM;
 unsigned short ID;
 int Size;
 int Checksum;
 UBYTE Format;
 UBYTE Encoding;
} XL_RecAnnDownloadInit;
```

## C++ Class

```
class XLC_RecAnnDownloadInit : public XLC_OutboundMessage
{
public:
 UBYTE getSlot() const;
 void setSlot(UBYTE x);
 UBYTE getSIMM() const;
 void setSIMM(UBYTE x);
 unsigned short getID() const;
 void setID(unsigned short x);
 int getSize() const;
 void setSize(int x);
 int getChecksum() const;
 void setChecksum(int x);
 UBYTE getFormat() const;
 void setFormat(UBYTE x);
 UBYTE getEncoding() const;
 void setEncoding(UBYTE x);
};
```

## EXS API Hex Format

| <b>Description</b>    | <p>This message is used to define the signaling received by the CSP for non-standard trunk or line interfaces on the ST1LC card.</p> <p>This message <b>cannot</b> be used with the T-ONE card. Line signaling for the T-ONE card is configured with T1 PPL Config Bytes 111–116 using the <i>PPL Configure</i> message.</p> <p><b>NOTE:</b> This message should not be used without first contacting Cantata Technical Support.</p> |

**Sent by** Host

**SwitchKit Code** **Configuration**

```
ReceiveSignalingConfig (
 Node = integer,
 Range = StartSpan:StartChan - EndSpan:EndChan,
 SignallingType = integer,
 SignallingValue = integer,
 TransmissionMode = integer,
 BitMask = integer);
```

**C Structure**

```
typedef struct {
 unsigned short StartSpan;
 UBYTE StartChannel;
 unsigned short EndSpan;
 UBYTE EndChannel;
 UBYTE SignallingType;
 UBYTE SignallingValue;
 UBYTE TransmissionMode;
 UBYTE BitMask;
} XL_ReceiveSignalingConfig;
```

**C++ Class**

```
class XLC_ReceiveSignalingConfig : public
 XLC_ChangeRangeMessage {
public:
 unsigned short getStartSpan() const;
 void setStartSpan(unsigned short x);
 UBYTE getStartChannel() const;
 void setStartChannel(UBYTE x);
 unsigned short getEndSpan() const;
 void setEndSpan(unsigned short x);
 UBYTE getEndChannel() const;
 void setEndChannel(UBYTE x);
 UBYTE getSignallingType() const;
```

```

void setSignallingType(UBYTE x);
UBYTE getSignallingValue() const;
void setSignallingValue(UBYTE x);
UBYTE getTransmissionMode() const;
void setTransmissionMode(UBYTE x);
UBYTE getBitMask() const;
void setBitMask(UBYTE x);
};

```

**Example—Inverting E&M Signaling**

This example shows the message sequence sent to invert the default E&M Wink Start receive signaling on a channel. The default E&M signaling values are: On-hook: A = 0, B = 0; all other signaling: A = 1, B = 1.

A separate message must be sent to change each signaling type. The examples below show the values which would be sent in each message.

|                   |                      |
|-------------------|----------------------|
| Signaling Type    | 0x01 (On-hook)       |
| Signaling Value   | 0x03 (A = 1, B = 1)  |
| Transmission Mode | 0x01 (A and B fixed) |
| Bit Mask          | 0x03 (A and B)       |

|                   |                        |
|-------------------|------------------------|
| Signaling Type    | 0x02 (Initial Inseize) |
| Signaling Value   | 0x00 (A = 0, B = 0)    |
| Transmission Mode | 0x01 (A and B fixed)   |
| Bit Mask          | 0x03 (A and B)         |

|                   |                          |
|-------------------|--------------------------|
| Signaling Type    | 0x03 (Secondary Inseize) |
| Signaling Value   | 0x00 (A = 0, B = 0)      |
| Transmission Mode | 0x01 (A and B fixed)     |
| Bit Mask          | 0x03 (A and B)           |

|                   |                                |
|-------------------|--------------------------------|
| Signaling Type    | 0x04 (Outseize Acknowledgment) |
| Signaling Value   | 0x00 (A = 0, B = 0)            |
| Transmission Mode | 0x01 (A and B fixed)           |
| Bit Mask          | 0x03 (A and B)                 |

|                   |                      |
|-------------------|----------------------|
| Signaling Type    | 0x05 (Answer)        |
| Signaling Value   | 0x00 (A = 0, B = 0)  |
| Transmission Mode | 0x01 (A and B fixed) |
| Bit Mask          | 0x03 (A and B)       |

|                   |                                     |
|-------------------|-------------------------------------|
| Signaling Type    | 0x06 (Post Outseize Acknowledgment) |
| Signaling Value   | 0x00 (A = 0, B = 0)                 |
| Transmission Mode | 0x01 (A and B fixed)                |
| Bit Mask          | 0x03 (A and B)                      |

| <b>Description</b>         | <p><b>NOTE:</b> This message applies to the DSP Series 2 card only.</p> <p>Use this message to start a file recording.</p> <p>You can select the channel and the DSP card, or let the Matrix Controller choose the DSP Card by leaving the DSP slot set to 0xFF. The Matrix Controller card reports back in the response which DSP Card has been selected.</p> <p>The Initial Silence Timer specifies how much silence is allowed before the card aborts the recording. The Final Silence Timer specifies how much silence is allowed before the silence triggers the card to stop recording voice.</p> <p>Any delay between the beginning of conversation and the beginning of recording can result into clipped recorded media. To alleviate this potential problem, Cantata recommends sending the <i>Record File Start</i> message before the conversation begins (before the <i>Resource Connect</i> message). Recording sessions involve a signal energy detection threshold, so the silence before conversation will not be recorded.</p> |

### SwitchKit Code C Structure

```
typedef struct {
 UBYTE AddrInfo[253];
} XL_RecordFileStop;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE reserved6[13];
 UBYTE AddrInfo[251];
} XL_RecordFileStopAck;
```

### C++ Class

```
class XLC_RecordFileStop : public XLC_OutboundMessage {
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 XBYTE getConferenceID() const;
 void setConferenceID(XBYTE x);
 XBYTE getParentConferenceID() const;
 void setParentConferenceID(XBYTE x);
 XBYTE getChildConferenceID() const;
 void setChildConferenceID(XBYTE x);
 XBYTE getSpan() const;
 void setSpan(XBYTE x);
 UBYTE getChannel() const;
 void setChannel(UBYTE x)
};
```

### C++ Class Response

```
class XLC_RecordFileStopAck : public XLC_OutboundMessage
{
public:
 unsigned short getStatus() const
 void setStatus(unsigned short x)
```

```
const UBYTE *getAddrInfo() const;
UBYTE *getAddrInfo();
void setAddrInfo(UBYTE *x);
XBYTE getConferenceID() const;
void setConferenceID(XBYTE x);
XBYTE getParentConferenceID() const;
void setParentConferenceID(XBYTE x);
XBYTE getChildConferenceID() const;
void setChildConferenceID(XBYTE x);
XBYTE getSpan() const;
void setSpan(XBYTE x);
UBYTE getChannel() const;
void setChannel(UBYTE x);
;
```

| <b>Description</b>          | <p>Use the <i>SK_RedundantAppPoolsQuery</i> message to determine which Redundant Application Pools (RAPs) are defined within the Low-Level Communicator. For example, using this message you can determine which application is the primary one. You cannot modify arguments in this query.</p> <p>The LLC responds to the original query with the message <i>SK_RedundantAppPoolsQueryAck</i>. The response contains a list of all currently defined RAPs within the LLC. The information given in the list can be used to query individual RAPs with <i>SK_RedundantAppQuery</i> or <i>SK_RedundantAppPoolMembersQuery</i>.</p> |
| <b>Syntax</b>               | <p>The data field of this message contains a sequence of null-terminated strings, where each string is the name of a RAP. See the following example:</p> <pre>Data[RAPa\ORAPb\ORAPc\0]</pre> <p>This indicates that there are three RAPs, named “RAPa”, “RAPb”, and “RAPc”.</p>                                                                                                                                                                                                                                                                                                                                                   |
| <b>Sent by</b>              | Monitoring application or Converged Services Administrator (CSA)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

```

# RedundantAppStatusMsg

---

**Type**     SwitchKit API message

**Description**     The LLC sends *SK\_RedundantAppStatusMsg* to notify members of a Redundant Application Pool (RAP) about any changes to the state of the RAP.

This message is sent when an application first registers for membership and when the status of a member application changes. Status changes include the following:

- An application registers for membership
- An application sends the *SK\_ReselectPrimaryApp* message
- An application deregisters from membership in the RAP
- An application changes to primary

**Sent by**     LLC

**Arguments**     You can modify the following arguments:

| Argument           | Description                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AppName            | AppName is the application name of the requesting application. The name can be obtained by calling <i>sk_getConnectionName()</i> .                                                     |
| RedundantAppPoolID | The RedundantAppPoolID is a string that uniquely identifies the class of application wishing to be treated as redundant applications.<br><br><b>Notes: RAP IDs are case sensitive.</b> |

| Argument         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RedundancyStatus | <p>Values defined for this argument are:</p> <ul style="list-style-type: none"> <li>• SK_RED_STATUS_REMOVED ( 0) - The specified application has been removed from the redundant application.</li> <li>• SK_RED_STATUS_PRIMARY (1) - The specified application is the primary app for the redundant app group.</li> <li>• SK_RED_STATUS_SECONDARY (2) - The specified application is a secondary application for the redundant application group.</li> <li>• SK_RED_STATUS_NO_PRIMARY (3) - There is no primary application for the redundant app group.</li> <li>• SK_RED_STATUS_MONITOR (4) - The specified application is a monitoring application of the redundant application group.</li> </ul> |

**C Structure**

## RegisterAsRedundantApp

---

**Type**     SwitchKit API message

**Description**     The ***SK\_RegisterAsRedundantApp*** message is used by the function **sk\_registerAsRedundant()**.

If an application needs to register for membership into a Redundant Application Pool (RAP), the application must call the function **sk\_registerAsRedundant()**. The function then uses the *SK\_RegisterAsRedundantApp* message to register the application for membership into a RAP.

To remove an application from a pool, the application calls the function **sk\_deregisterAsRedundant()**, which then also uses the message to take a member out of the pool.

A ***SK\_RegisterAsRedundantAppAck*** message is an acknowledgment by the LLC, indicating the completion of the original request.

**Sent by**     Function **sk\_registerAsRedundant()**

**Arguments**     You can modify the following arguments:

| Argument           | Description                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AppName            | AppName is the application name of the requesting application. The name can be obtained by calling <i>sk_getConnectionName()</i> .                                                     |
| RedundantAppPoolID | The RedundantAppPoolID is a string that uniquely identifies the class of application wishing to be treated as redundant applications.<br><br><b>Notes: RAP IDs are case sensitive.</b> |

| Argument             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RedundantAppPriority | <p>RedundantAppPriority is a value indicating the current priority of the application. The higher the value, the more likely it is that the LLC will select the application as primary. Predefined values are:</p> <p><b>SK_RED_APP_PRI_MONITOR (0)</b><br/>Used by an application wishing to monitor the activity of this RedundantAppClass. An application selecting this priority cannot be considered either primary or secondary.</p> <p><b>SK_RED_APP_PRI_REMOVED (-1)</b><br/>Used when an application needs to be removed from an RedundantAppClass for which it has previously registered.</p> |
| DataSize             | Size of the data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Data                 | Data bytes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>C Structure</b>   | <pre>typedef struct {     BaseFields Base;     unsigned short StartSpan;     unsigned short EndSpan;     UBYTE StartChannel;     UBYTE EndChannel;     char ChannelGroup[45];     UBYTE reserved68[16]; } <b><i>SK_RemoveChannelsFromGroup</i></b>;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>C++ Class</b>     | <pre>class <b><i>SKC_RemoveChannelsFromGroup</i></b>: public     SKC_AdminMessage { public:     SKC_RemoveChannelsFromGroup(int sz = 0);     ~SKC_RemoveChannelsFromGroup();     SK_DECLARE_CLASS(SKC_RemoveChannelsFromGroup, SKC_Admin         Message)     virtual MsgStruct *getStructPtr();     virtual const MsgStruct *getStructPtr() const;     virtual int getTag() const;     unsigned short getStartSpan() const;     void setStartSpan(unsigned short x);     unsigned short getEndSpan() const;     void setEndSpan(unsigned short x);     UBYTE getStartChannel() const;     void setStartChannel(UBYTE x);     UBYTE getEndChannel() const;     void setEndChannel(UBYTE x);     const char *getChannelGroup() const;     void setChannelGroup(const char *x); };</pre> |

**Example** The following is an example of *RemoveChannelsFromGroup* for Channel Group “all”, with a range of span 0/channel 2 - span 1/channel 3.

```
RemoveChannelsFromGroup(
 ChannelGroup="all",
 Range=0:2-1:3);
```

# RemoveLLCRoutingID

---

**Type** SwitchKit API message

**Overview** This message will remove an individual RoutingID from the LLC but leave the connection to the card and all other RoutingID's established even after the last RoutingID is removed. However, if an attempt is made to remove the last RoutingID before removing the connection, the LLC will log a message stating that the devices have been orphaned and will then remove the RoutingID. At this point the LLC maintains communications with the card pair but the socket pair is reported as being down so that applications will not attempt to send/receive messages to it. After a pair of devices have been orphaned (all RoutingID's have been removed), routing and communications for an application can be re-established without establishing a new connection by configuring a new RoutingID for that card IP pair using the *AddLLCCard* message.

**Sent by** Application

**C Structure**

```
typedef struct {
 BaseFields Base;
 int RoutingID;
 unsigned short CardType;
 UBYTE reserved23[4];
} SK_RemoveLLCRoutingID;
```

**C Structure Response**

```
typedef struct {
 BaseFields Base;
 int Status;
 int RoutingID;
 UBYTE Reserved1;
 UBYTE reserved26[5];
} SK_RemoveLLCRoutingIDAck;
```

**C++ Class**

```
class SKC_RemoveLLCRoutingID : public
 SKC_ToolkitMessage {
public:
 SKC_RemoveLLCRoutingID(int sz = 0);
 ~SKC_RemoveLLCRoutingID();

 SK_DECLARE_CLASS(SKC_RemoveLLCRoutingID,SKC_ToolkitMes
 sage)

 virtual MsgStruct *getStructPtr();
```

## RemoveLLCRoutingID

```
virtual const MsgStruct *getStructPtr() const;
virtual int getTag() const;
```

```
int getRoutingID() const;
void setRoutingID(int x);
unsigned short getCardType() const;
void setCardType(unsigned short x);
```

### C++ Class Response

```
class SKC_RemoveLLCRoutingIDAck : public
 SKC_ToolkitAck {
public:
 SKC_RemoveLLCRoutingIDAck(int sz = 0);
 ~SKC_RemoveLLCRoutingIDAck();

 SK_DECLARE_CLASS(SKC_RemoveLLCRoutingIDAck, SKC_Toolkit
 Ack)

 virtual MsgStruct *getStructPtr();
 virtual const MsgStruct *getStructPtr() const;
 virtual int getTag() const;

 int getStatus() const;
 void setStatus(int x);
 int getRoutingID() const;
 void setRoutingID(int x);
 UBYTE getReserved1() const;
 void setReserved1(UBYTE x);
```

### RemoveLLCRoutingIDAck

The LLC will acknowledge the RemoveLLCRoutingIDAck with a RemoveLLCRoutingAck message.

```
RemoveLLCRoutingIDAck (Status=<**Response Value>
RoutingID= <Unique ID for Card Pair>,
Reserved1= <Not currently used>);
```

### Status Field

Possible Response Values found in the Status field of an RemoveLLCRoutingIDAck Message.

| **Response Values | Action                                                    |
|-------------------|-----------------------------------------------------------|
| SK_SUCCESS        | The RoutingID was successfully removed.                   |
| SK_NOT_PRESENT    | The RoutingID was not found.                              |
| SK_NO_MESSAGE     | Invalid message parameter found while processing request. |

### RoutingID Macros

To avoid duplicate values, the routing ID for each type of sub-component card must be derived using that cards corresponding get\_RoutingID macro. Macros will be defined within SK\_API.h so that they are globally accessible.

### Macros available for deriving RoutingID's

| CardType                   | Function                                  |
|----------------------------|-------------------------------------------|
| SK_SS7TCAP_BOARD<br>(0x03) | getSS7TCAP_RoutingID(int stackid(0-255)); |

# RequestChannelAck

| <b>Description</b> | <p>The LLC sends this message as a response to a previously sent <b>sk_requestOutseizedChannel()</b> or <b>sk_requestChannel()</b>. It notifies the application that a channel has been assigned to it, which must later be returned with <b>sk_returnChannel()</b>. It is important to note that even in the case of a SK_OUTSEIZE_NACK, a channel has been assigned to the application which must be returned.</p> <p>To check the return status, you should first check SKStatus. Only if SKStatus contains SK_OUTSEIZE_NACK should XLStatus be examined. Otherwise, XLStatus will contain invalid data.</p> <p>SKStatus will contain one of the following values:</p> <ul style="list-style-type: none"> <li>• OK - the channel referenced by “Span/Channel” was successfully outseized. Span/Channel is considered allocated to this application, and must be returned through sk_returnChannel when the application is done with it.</li> <li>• SK_OUTSEIZE_NACK - the channel Span/Channel received an XLStatus nack from the Outseize attempt. This will only be returned after the number of retries specified in the <b>sk_requestOutseizedChannel()</b> have all been tried and failed. The last Span, Channel whose outseize failed is considered allocated to this application, and must be returned through <b>sk_returnChannel()</b> when the application is done with it.</li> <li>• SK_NO_CHANNELS - none of the channels in the requested group were available. The channels might be unavailable because they’re in use, out of service, or in yellow or red alarm. In this case, Span/Channel will contain invalid data, as no channel has been assigned to the application.</li> </ul> |

| <b>Description</b>                         | <p>This message is sent to the host when an incoming call is detected on the specified channel and the specified channel was previously configured to “report incoming call with digits.”</p> <p>For SS7, the system uses this message as a response to an IAM message from the network. By default, BT IUP parameters are reported to the host in a BT IUP parameters ICB. The host can modify this to have address data sent as BCD-encoded digits.</p> <p>SIP endpoints report incoming calls from the SIP side using the <i>Request for Service with Data</i> message. The data type Universal Data (0x33) is for SIP calls. The UPDF parameters supported are the same as those supported in the <i>Route Control</i> message.</p> <p>H.323 endpoints report incoming calls from the H.323 side using the <i>Request for Service with Data</i> message. The data type Universal Data (0x33) is for H.323 calls. The UPDF parameters supported are the same as those supported in the <i>Route Control</i> message.</p> |

Stage Status

The system reports the stage status for each of the five stages. Timers can be configured.

Valid entries for this field are as follows:

0x10 Positive Acknowledgment – Digits received

0x80 Partial Dial Condition – Receive Inter-digit Duration timer expired

0x81 Permanent Signal Condition – Receive 1st Digit Detection Timer expired

0x91 Inpulse Stage Not Collected – Stage not collected; no further stage information will be reported.

0x92 Digit Complete Timeout

#### NOTES:

- 1 Each stage may contain up to two strings.
- 2 Valid responses to this message may also be *Connect*, *Connect With Pad*, *Connect One-Way Forced*, *Connect With Data*, *Connect Wait*, *Connect To Conference*, *Connect One-Way To Conference*, and *Park Channel*.

#### 0x04 Q.931 Received Frame

This data is allowed for the ISDN interface only and will be the exact data received from the distant end (see ITU Q.931).

## Reselect Primary App

---

**Type** SwitchKit API message

**Description** Use the *SK\_ReselectPrimaryApp* message to indicate to the LLC that the primary application should be selected for a specific Redundant Application Pool (RAP). By default, the first application to connect to the LLC is the primary application. You can change which application is designated as primary, using the appropriate variable. After receiving this message, the LLC looks at all members of a RAP and selects a new primary application for the RAP. The Flag field dictates the behavior of this command as described in the arguments table further on this page.

If the LLC selects a new primary application, all members of the specific RAP are notified about the change in status, including the indication.

The *SK\_ReselectPrimaryAppAck* is the response to the initial *SK\_ReselectPrimaryApp* message, and it indicates the success or failure of the reselect.

**Sent by** Application

**Arguments** The following table shows the arguments that you can modify:

| Argument           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b>    | <p>This message resets a card's configuration to the default values by corrupting the battery-backed configuration and initiating a hardware reset on the local processor. To reset the configuration on a Matrix Controller, all cards must be specified and the force flag must be set.</p> <p>This message is useful for completely reinitializing the CSP or any component in the CSP. Generally, it should not be used on a live system.</p> <p>For SwitchKit, if you have included <i>ResetConfig</i> messages in your configuration file, the <i>ConfigStage</i> must be set to 10 for a reset to be performed. If the <i>ConfigStage</i> is anything other than 10, the reset is ignored.</p> |

**Notes:**

1. When resetting a line card's configuration, the host must wait for a *Card Status Report* message on the specified line card before considering its configuration reset.
2. Switchover will occur if all cards in the system are specified and there is a standby Matrix Controller present.
3. The Matrix Controller that gains control of the system after you send the *Reset Configuration* message becomes the active Matrix Controller. This Matrix Controller may not necessarily be the one that was active before you sent the message.

## Reset IP Signaling Series 3 Card 0x0107

| <b>Description</b>     | <p>This message resets the IP Signaling Series 3 card before and/or after the IP Signaling Series 3 Card Interface is established. This message is sent directly to the IP Signaling Series 3 card and uses the extended logical node ID format.</p> <p>You can also reset the IP Signaling Series 3 card using the <i>Reset Configuration 0x000B</i> message once the IP Signaling Series 3 Card Interface is established.</p>                                                                                                                                                                                                                                                             |
| <b>Sent by</b>         | Host                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

# Reset Matrix 0x009D

---

**SwitchKit Name** ResetMatrix

**Type** EXS API or SwitchKit API message

**Description** This message is used by the host to force a matrix to reset. If the host sends it to the active Matrix Controller in a redundant system, it will result in a Matrix Controller switchover. A switchover can also be initiated by sending a *Become Active* message to the standby Matrix Controller card.

**Sent by** Host

**Related API Messages** *Become Active* 0x00A1 (ActivateMatrix)

**SwitchKit Code** **C Structure**

```
typedef struct {
 } XL_ResetMatrix;
```

**C++ Class**

```
class XLC_ResetMatrix : public XLC_OutboundMessage {
public:
 };
```

| <b>SwitchKit Name</b> | ResourceAttributeQuery                                                                                                         |
| <b>Type</b>           | EXS API and SwitchKit API message                                                                                              |
| <b>Description</b>    | This message queries either the default attributes of a module, or the current attributes of a channel involved in an IP call. |
| <b>Sent By</b>        | Host                                                                                                                           |

### SwitchKit Code C Structure

```
typedef struct {
 UBYTE Slot;
 UBYTE DataType;
 UBYTE TLVCount;
 UBYTE Data[221];
} XL_ResourceAttributeQuery;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE Slot;
 UBYTE TLVCount;
 UBYTE Data[220];
} XL_ResourceAttributeQueryAck;
```

### C++ Class

```
class XLC_ResourceAttributeQuery : public
 XLC_OutboundMessage {
public:
 UBYTE getSlot() const;
 void setSlot(UBYTE x);
 UBYTE getDataType() const;
 void setDataType(UBYTE x);
 UBYTE getTLVCount() const;
 void setTLVCount(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

### C++ Class Response

```
class XLC_ResourceAttributeQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getSlot() const;
 void setSlot(UBYTE x);
 UBYTE getTLVCount() const;
```

```

void setTLVCount(UBYTE x);
const UBYTE *getData() const;
UBYTE *getData();
void setData(UBYTE *x);
};

```

### EXS API Hex Format

### Tag/Length/Value Blocks

Only one format of the Address Element Block TLV is required.

If the TLV contains the data type of Expanded Span/Channel, then the message is querying attributes of an established call.

If the TLV contains the data type of IP Address, then the message is querying default attributes of all channels associated with a particular DSP.

**Message TLVs      Address Element TLV Block**  
*(for the Expanded Span/Channel AIB)*

| Byte | Description                                              |
|------|----------------------------------------------------------|
| 0, 1 | Tag: Address Element Block (0x0009)                      |
| 2, 3 | Length: 0x0005                                           |
| 4    | Value: Data[0] AIB Type:<br>Expanded Span/Channel (0x0D) |
| 5    | Value: Data[1] AIB Length (0x03)                         |
| 6    | Value: Data[2] Logical Span (MSB)                        |
| 7    | Value: Data[3] Logical Span (LSB)                        |
| 8    | Value: Data[4] Channel                                   |

**Address Element TLV Block**  
*(for the IP Address AIB)*

| Byte | Description                                 |
|------|---------------------------------------------|
| 0, 1 | Tag: Address Element Block (0x0009)         |
| 2, 3 | Length: 0x0006                              |
| 4    | Value: Data[0] AIB Type: (0x3E: IP Address) |
| 5    | Value: Data[1] AIB Length (0x04)            |
| 6    | Value: Data[2] IP (MSB)                     |
| 7    | Value: Data[3] IP                           |
| 8    | Value: Data[4] IP                           |
| 9    | Value: Data[5] IP (LSB)                     |

# Resource Connect 0x0127

---

|                       |                                            |
|-----------------------|--------------------------------------------|
| <b>SwitchKit Name</b> | ResourceConnect                            |
| <b>Type</b>           | EXS and SwitchKit API message              |
| <b>Description</b>    | Use this message to connect to a resource. |

## Connect to a Child Conference

Use the Channel AIB and the Child Conference AIB. The Channel AIB indicates the Channel to be moved from the parent conference to the child conference. The Child Conference ID AIB indicates both the parent and child conference IDs.

**NOTE:** For the SwitchKit code, you must specify the span and channel before you specify the conference ID.

**Sent by** Host application

Mandatory TLVs

0x0602 Resource Type  
(This is the B Resource Type)

If the Resource Type is Send or Receive Fax:

0x05E0 File ID

0x05E2 File Location

If the Resource Type is set to Send SMS (0x010A) or Receive SMS (0x010B):

0x0694 SMS Data

Optional TLVs

If AIB is Conference and Resource Type is Conference:

0x0604 DTMF Clamping/Filtering Enable (Default is Disabled)

0x0607 Output Gain Control (Default is 0db)

0x0608 Noise Gating Enable (Default is Disabled)

0x060A Echo Suppression Enable (Default is Disabled)

0x060C Automatic Gain Control Enable (Default is Disabled)

0x0612 Connection Type

0x060F Conference Failure Behavior

0x068B Input Gain Control

0x068D Transit Connection Mode

Optional TLVs

If AIB is Child Conference ID and Resource Type is Conference:

0x0604 DTMF Clamping/Filtering Enable (Default is Disabled)

0x0607 Output Gain Control (Default is 0db)

0x0608 Noise Gating Enable (Default is Disabled)

0x060A Echo Suppression Enable (Default is Disabled)

0x060C Automatic Gain Control Enable (Default is Disabled)

# Resource Create 0x0124

---

**SwitchKit Name** Resource Create

**Type** EXS and SwitchKit API message

**Description** Use this message to create a processing resource in the CSP.

## Conference

To create a Unified conference, you send the following:

AIB: DSP Chip

Resource Type TLV: Conference

TLVs

Channel/DSP Pool

Conference Size

Monitor Conference Enable (to create a Monitor Conference)

Any optional conference TLVs

The Conference ID is returned in the response.

## Child Conference

To create a Child Conference, you send the following:

AIB: Child Conference ID

TLVs

Resource Type: Child Conference

Any optional conference TLVs

The Child Conference ID is returned in the response.

**Sent by** Host application

**Related API Messages** *Resource Modify* (0x125)  
*Resource Delete* (0x126)  
*Resource Connect* (0x127)

**SwitchKit Code** **C Structure**

```
typedef struct {
 UBYTE AddrInfo[30];
 UBYTE DataType;
 UBYTE TLVCount;
 UBYTE Data[221];
} XL_ResourceCreate;
```

**C Structure Response**

```
typedef struct {
 unsigned short Status;
 UBYTE reserved6[13];
 UBYTE AddrInfo[30];
 UBYTE DataType;
 UBYTE TLVCount;
 UBYTE Data[219];
} XL_ResourceCreateAck;
```

**C++ Class**

```
class XLC_ResourceCreate : public XLC_OutboundMessage {
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 XBYTE getParentConferenceID() const;
 void setParentConferenceID(XBYTE x);
 XBYTE getChildConferenceID() const;
 void setChildConferenceID(XBYTE x);
 UBYTE getDSPChip() const;
 void DSPChip(UBYTE x);
 UBYTE getDSPSlot() const;
 void setDSPSlot(UBYTE x);
 UBYTE getDSPSIMM() const;
 void setDSPSIMM(UBYTE x);
 UBYTE getDataType() const;
 void setDataType(UBYTE x);
 UBYTE getTLVCount() const;
 void setTLVCount(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
}
```

**C++ Class Response**

```
class XLC_ResourceCreateAck: public
XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 XBYTE getParentConferenceID() const;
 void setParentConferenceID(XBYTE x);
 XBYTE getChildConferenceID() const;
 void setChildConferenceID(XBYTE x);
 UBYTE getDSPChip() const;
 void DSPChip(UBYTE x);
 UBYTE getDSPSlot() const;
 void setDSPSlot(UBYTE x);
 UBYTE getDSPSIMM() const;
```

```
void setDSPSIMM(UBYTE x);
UBYTE getDataType() const;
void setDataType(UBYTE x) ;
UBYTE getTLVCount() const ;
void setTLVCount(UBYTE x) ;
const UBYTE getDataType() const;
UBYTE *getData() ;
void setDataType(UBYTE x);
};
```

**EXS API Hex Format**

# Resource Delete 0x0126

---

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <b>SwitchKit Name</b> | ResourceDelete                                    |
| <b>Type</b>           | EXS API and SwitchKit API message                 |
| <b>Description</b>    | Use this message to delete a processing resource. |

## Deleting a Conference

If forced deletion of a child conference is specified, the child conference is deleted immediately and the parties are connected back to the parent conference. If graceful deletion of a child conference is specified, then the child conference is deleted only after all the parties connected to it are disconnected. If the Forced Delete TLV is not used, graceful deletion is the default behavior.

When you use this message to delete a child conference, you must use the Child Conference ID AIB to address the child conference that needs to be deleted. If the child conference ID is specified as FFFF, then all the child conferences for the particular parent conference are deleted.

# Resource Delete Indication 0x0129

---

## SwitchKit Name

**Type** EXS API and SwitchKit API message

**Description** This message indicates that a resource has been deleted.

### Conferencing

When a child conference has been deleted, this message uses the Child Conference ID AIB as well as the mandatory AIB Container TLV (0xE003).

**Sent by** CSP

**Related API Messages**

# Resource Disconnect 0x0128

---

**SwitchKit Name** ResourceDisconnect

**Type** EXS and SwitchKit API message

**Description** Use this message to disconnect a processing resource, which was previously connected using the *Resource Connect* message.

## FAX

Use this message to disconnect a fax channel in order to interrupt fax processing on that channel.

## Conferencing

Use this message to move a channel from a Child Conference back into the Parent Conference. Use the Channel AIB and the Child Conference AIB. The Channel AIB indicates the Channel to be moved from the child conference to the parent conference. The Child Conference ID AIB both the parent and child conference IDs.

**Sent by** Host application

# Resource Information Notify 0x0141

---

**SwitchKit Name** ResourceInfoNotify

**Type** EXS and SwitchKit API message

**Description** Use this message to connect to a resource.

## Connecting to a different resource types

Use this generic message to specify different Resource Types. When used for Frequency Shift Keying (FSK), the mandatory Resource Type TLV 0x0602 will be set to either Send SMS (0x010C) or Receive SMS (0x010D) and from the Switch to notify the Host of the SMS data received by the DSP Series 2 card.

**Sent by** Switch application

**Related API Messages** *Resource Create* (0x0124)  
*Resource Modify* (0x125)  
*Resource Delete* (0x126)

**SwitchKit Code** **C Structure**

```
typedef struct {
 UBYTE AddrInfo[30];
 UBYTE DataType;
 UBYTE TLVCount;
 UBYTE Data[221];
} XL_ResourceInfoNotify;
```

## C++ Class

```
class XLC_ResourceInfoNotify: public XLC_OutboundMessage {
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 XBYTE getParentConferenceID() const;
 void setParentConferenceID(XBYTE x);
 XBYTE getChildConferenceID() const;
 void setChildConferenceID(XBYTE x);
 UBYTE getDataType() const;
 void setDataType(UBYTE x);
 UBYTE getTLVCount() const;
 void setTLVCount(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**EXS API Hex Format**

| <b>Description</b>          | <p>Use this message to query different configuration parameters that have been set for a particular channel (or any other entity used as an A-resource) using the <i>Resource Connect</i> (0x0127), <i>Resource Create</i> (0x0124), or <i>Resource Modify</i> (0x0125) messages.</p> <p>You can use this message to query fax configuration parameters set for a particular channel on a per-call basis. These optional fax configuration parameters would have been configured while initiating a fax call, using the <i>Resource Connect</i> message (0x0127).</p> <p><b>Note:</b> To query configuration parameters that have been set at the card level using the <i>Generic Card Configure</i> (0x0122) message, use the <i>Generic Card Query</i> message (0x023).</p> |

## Resource Release Indication 0x012E

---

**SwitchKit Name** ResourceReleaseIndication

**Type** EXS and SwitchKit API message

**Description** Use this message to connect to a resource.

### Connecting to a different resource types

Use this generic message to specify different Resource Types. When used for Frequency Shift Keying (FSK), the mandatory Resource Type TLV 0x0602 will be set to either Send SMS (0x010C) or Receive SMS (0x010D) and sent from the Switch to the Host to indicate a SMS call release at the Data Link Layer.

**Sent by** Switch application

**Related API Messages** *Resource Create* (0x0124)  
*Resource Modify* (0x125)  
*Resource Delete* (0x126)

**SwitchKit Code** **C Structure**

```
typedef struct {
 UBYTE AddrInfo[30];
 UBYTE DataType;
 UBYTE TLVCount;
 UBYTE Data[221];
} XL_ResourceReleaseIndication;
```

### C++ Class

```
class XLC_ResourceReleaseIndication: public
 XLC_OutboundMessage {
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 XBYTE getParentConferenceID() const;
 void setParentConferenceID(XBYTE x);
 XBYTE getChildConferenceID() const;
 void setChildConferenceID(XBYTE x);
 UBYTE getDataType() const;
 void setDataType(UBYTE x);
 UBYTE getTLVCount() const;
 void setTLVCount(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**EXS API Hex Format**

## Resource Release Request 0x012D

---

**SwitchKit Name** ResourceReleaseRequest

**Type** EXS and SwitchKit API message

**Description** Use this message to connect to a resource.

### Connecting to a different resource types

Use this generic message to specify different Resource Types. When used for Frequency Shift Keying (FSK), the mandatory Resource Type TLV 0x0602 will be set to either Send SMS (0x010C) or Receive SMS (0x010D) and sent from the Host to the switch to release the Data Link Layer connection in a SMS call.

**Sent by** Host application

**Related API Messages** *Resource Create* (0x0124)  
*Resource Modify* (0x125)  
*Resource Delete* (0x126)

**SwitchKit Code** **C Structure**

```
typedef struct {
 UBYTE AddrInfo[30];
 UBYTE DataType;
 UBYTE TLVCount;
 UBYTE Data[221];
} XL_ResourceReleaseRequest;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE reserved6[13];
 UBYTE AddrInfo[30];
 UBYTE DataType;
 UBYTE TLVCount;
 UBYTE Data[219];
} XL_ResourceReleaseRequestAck;
```

### C++ Class

```
class XLC_ResourceReleaseRequest: public
 XLC_OutboundMessage {
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 XBYTE getParentConferenceID() const;
 void setParentConferenceID(XBYTE x);
```

```

XBYTE getChildConferenceID() const;
void setChildConferenceID(XBYTE x);
XBYTE getSpan() const;
void setSpan(XBYTE x);
UBYTE getChannel() const;
void setChannel(UBYTE x);
UBYTE getDataType() const;
void setDataType(UBYTE x);
UBYTE getTLVCount() const ;
void setTLVCount(UBYTE x) ;
const UBYTE *getData() const ;
UBYTE *getData();
void setData(UBYTE *x) ;
};

```

### C++ Class Response

```

class XLC_ResourceReleaseRequestAck : public
XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 XBYTE getParentConferenceID() const;
 void setParentConferenceID(XBYTE x);
 XBYTE getChildConferenceID() const;
 void setChildConferenceID(XBYTE x);
 XBYTE getSpan() const;
 void setSpan(XBYTE x);
 UBYTE getChannel() const;
 void setChannel(UBYTE x);
 UBYTE getDataType() const;
 void setDataType(UBYTE x);
 UBYTE getTLVCount() const ;
 void setTLVCount(UBYTE x) ;
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};

```

# Ring Status Query 0x0071

---

|                                    |                                                                                                                                                               |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SwitchKit Name</b>              | RingStatusQuery                                                                                                                                               |
| <b>Type</b>                        | EXS API and SwitchKit API message                                                                                                                             |
| <b>Description</b>                 | Use this message to query either the ring status or the ring configuration.                                                                                   |
| <b>To Query Ring Configuration</b> | Use the Ring Configuration Query address type in the AIB to query the ring configuration. See “Response Data” for the format of the data returned by the CSP. |
| <b>Sent by</b>                     | Host                                                                                                                                                          |
| <b>SwitchKit Code</b>              | <b>C Structure</b>                                                                                                                                            |

```
typedef struct {
 UBYTE AddrInfo[253];
} XL_RingStatusQuery;
```

## C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE Slot;
 UBYTE Data[221];
} XL_RingStatusQueryAck;
```

## C++ Class

```
class XLC_RingStatusQuery : public XLC_OutboundMessage {
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 UBYTE getSlot() const;
 void setSlot(UBYTE x);
};
```

## C++ Class Response

```
class XLC_RingStatusQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getSlot() const;
 void setSlot(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**Overview of message** The following table provides an overview of this message. The table following it, provides the detail for each byte.

| MESSAGE (White) |                         | RESPONSE (Gray) |                       |

### Response Data      Ring Configuration Query

When querying the ring configuration, the following Data is returned.

| RESPONSE FIELDS FOR RING CONFIGURATION QUERY                                |                                 |
|-----------------------------------------------------------------------------|---------------------------------|
| Data[0] Number of Rings Configured                                          |                                 |

|                                                                             | Data[8] Logical Node ID         |
|                                                                             | Data[9] Load Major Rev.         |
|                                                                             | Data[10] Load Minor Rev.        |
|                                                                             | Data[11] Load Build Number      |
|                                                                             | Data[12] Transmit/Receive Mode  |

Data[0] Number of Rings Configured

Data[1] Number of Unconfigured Nodes

**NOTE:** Data[2-12] is reported for each ring in the system.

Data[2] Logical Ring ID  
Data[3] Ring Service State  
    0x00 Out of Service  
    0x01 In Service  
Data[4] Number of Nodes on Ring  
Data[5] Ring Master Node ID

**NOTE:** Data[6-12] is repeated for each node on the ring.

Data[6] Logical Node ID  
Data[7] Physical Node ID  
Data[8] IP Address  
Data[9] Load Major Revision  
    0x00 Unavailable  
    0x01 Major Revision Number of the Load on the Matrix greater  
Data[10] Load Minor Revision  
    0x00 Unavailable  
    0x01 Minor Revision Number of the Load on the Matrix greater  
Data[11] Load Build Number  
    0x00 Unavailable  
    0x01 Build Number of the Load on the Matrix greater  
Data[12] Transmit/Receive Mode  
    0x00 Receive Only  
    0x01 Transmit and Receive

# Ring Status Report 0x0072

---

**Redundancy State** This field indicates redundancy state of the RICs:

0x00 No Redundancy  
0x01 Active RIC  
0x02 Standby RIC  
0xFF Role Not Yet Defined

**Current Ring Mode** This field indicates the Ring Mode:

0x00 Normal Ring Mode  
0x01 Enhanced Fault Tolerance Ring Mode

## Route Control 0x00E8

---

**SwitchKit Name** Route Control

**Type** EXS API and SwitchKit API message

**Description** Use this message to outseize to a channel using the CSP Call Control. If you want to the host application to choose the span/channel, use the *Outseize Control* message instead of this message.

Contact Cantata Technical Support if you want to send a *Route Control* message greater than 512 bytes.

**Sent by** Host

**Protocol-Specific Considerations** This section provides protocol-specific considerations to help you use this message for VoIP calls. Note that these are examples and that there are several other ways to use the *Route Control* message.

The mandatory TLVs are listed for each ICB, but other protocol specific TLVs are mandatory in order to initiate an outbound call. Moreover, you may include additional optional TLVs as needed.

### SIP

For physical SIP calls, the *Route Control* message must contain the following:  
AIB - 0x0029 - Generic Router

### Extended ICBs

0x001E Generic PPL ICB

0x0013 Routing Method TLV  
Value: 0x0008 Criteria Type

0x000F Router Protocol ID TLV  
Value: 0x000B Default Router

0x0008 Criteria Type TLV  
Value: 0x0065 Physical VoIP Channel

0x0065 Physical VoIP Channel TLV  
Value: 0x0000 (reserved)

0x0033 NPDI Universal ICB

Route Control 0x00E8

0x277E Remote Side Protocol TLV  
Value: 0x08 - SIP

### **H.323**

For H.323 calls, the *Route Control* message must contain the following:

AIB - 0x0029 - Generic Router

#### *Extended ICBs*

0x001E Generic PPL ICB

0x0013 Routing Method TLV  
Value: 0x0008 Criteria Type

0x000F Router Protocol ID TLV  
Value: 0x000B Default Router

0x0008 Criteria Type TLV  
Value: 0x0065 Physical VoIP Channel

0x0065 Physical VoIP Channel TLV  
Value: 0x0000 (reserved)

0x0033 NPDI Universal ICB

0x277E Remote Side Protocol TLV  
Value: 0x09H.323

0x27C2 Remote End Signaling IP Address (Q.931) TLV  
Value: IP Address

### **SIP Call Agent**

For Call Agent calls, the *Route Control* message must contain the following:

AIB - 0x0029 - Generic Router

#### *Extended ICBs*

0x001E Generic PPL ICB

0x0013 Routing Method TLV  
Value: 0x0008 Criteria Type

0x000F Router Protocol ID TLV  
Value: 0x000B Default Router

0x0008 Criteria Type TLV

Value: 0x0071 Virtual VoIP Channel

0x0071 Virtual VoIP Channel TLV

Value: 0x0000 (reserved)

0x0033 - NPDI Universal ICB

0x277E Remote Side Protocol TLV

Value: 0x08SIP

### **Interworking**

For Interworking calls, the *Route Control* message must contain the following:

AIB - 0x0029 - Generic Router

### ***Extended ICBs***

0x001E Generic PPL ICB

0x0013 Routing Method TLV

Value: 0x0008 Criteria Type

0x000F Router Protocol ID TLV

Value: 0x000B Default Router

0x0008 Criteria Type TLV

Value: 0x0065 Physical VoIP Channel

0x0065 Physical VoIP Channel TLV

Value: 0x0000 (reserved)

0x0033 NPDI Universal ICB

0x277E Remote Side Protocol TLV

Value: 0x08SIP

### **Clear Channel VoIP**

For Clear Channel VoIP calls, the *Route Control* message must contain the following:

ICBs

0x001E Generic PPL ICB or 0x1E Generic PPL ICB

0x0013 Routing Method TLV

Value: 0x0009 Terminating Channel

0x0009 Terminating Channel TLV

Refer to the *Developer's Guides* for examples that include the *Route Control* message.

## SwitchKit Code    **C Structure**

```
typedef struct {
 UBYTE AddrInfo[30];
 UBYTE ICBCount;
 UBYTE Data[222];
} XL_RouteControl;
```

## **C Structure Response**

```
typedef struct {
 unsigned short Status;
 UBYTE Data[251];
} XL_RouteControlAck;
```

## **C++ Class**

```
class XLC_RouteControl : public XLC_OneChannelOutbound {
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 XBYTE getSpan() const;
 void setSpan(XBYTE x);
 UBYTE getChannel() const;
 void setChannel(UBYTE x);
 XBYTE getRouterHandle() const;
 void setRouterHandle(unsigned short x);
 UBYTE getICBCount() const;
 void setICBCount(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

## **C++ Class Response**

```
class XLC_RouteControlAck : public XLC_AcknowledgeMessage
{
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**Overview of message** The following table provides an overview of this message. The table following it, provides the detail for each byte.

| MESSAGE (White)  |                                                         | RESPONSE (Gray) |                       |

| <b>Description</b> | The LLC sends the <i><b>ServerStatusChange</b></i> message containing all the information needed by an application to determine the current status of a node. The message is sent when the LLC discovers a change in CSP status.                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>C Structure</b> | <pre>typedef struct {     unsigned short Status;     UBYTE SystemType;     UBYTE MatrixSide;     UBYTE MatrixState;     UBYTE AdjMatrixState;     UBYTE StatusBits;     UBYTE Reserved1;     UBYTE Reserved2;     unsigned short ExcelPort;     int PhysicalNode;     UBYTE LogicalNode;     UBYTE HostNode;     UBYTE NodeStatus;     UBYTE MessageTrigger;     UBYTE FromPrimary;     UBYTE SocketStatus;     unsigned short UpdatedFieldBits;     UBYTE reserved40[1]; } <i><b>SK_ServerStatusChange</b></i>;</pre>                                                                                                    |

};

```

### Conditions for Sending the ServerStatusChange Message

The following list shows the conditions that will cause the LLC to send a *ServerStatusChange* message:

- SK\_PM\_CHANGE - sent when the first poll is received by the LLC for a . Also sent any time a value changes in the Poll. The UpdatedFieldBits field indicates which fields have changed since the last poll.
- SK\_SSC\_UPDATE - sent under the following conditions:
  1. When an application registers for the ServerStatusChange notification via *sk\_msgRegister()*, an SSC\_UPDATE is sent for each node the LLC is currently connected to which has a in the active state.
  2. When an application issues an *AddLLCNode*, an SSC\_UPDATE may be generated if the LLC already knew about the node and the LLC is currently connected to the active for that node. In other words, if the Link is considered to be up.
- SK\_LINK\_UP - sent under the following conditions:

1. This message is sent to indicate that there is a connection to the active for this node and the is ready to be configured. This will be sent if this is a new condition (i.e. we were not previously connected to the active ).
  2. Sent if an application has performed an *AddLLCNode*, the LLC is currently connected to the specified node, and the LLC is connected to the active of that node.
  3. When an application registers for the *ServerStatusChange* notification via *sk\_msgRegister()*, and the LLC is connected to the active of a node.
- SK\_LINK\_DOWN - sent under the following conditions:
    1. This message is sent to indicate that there is NO connection to the active for a node. This will be sent if this is a new condition (that is, we were previously connected to the active MSP 1010).
    2. Sent if an application has performed an *AddLLCNode*, and the LLC is not currently connected to the specified node's active .
    3. When an application registers for the *ServerStatusChange* notification via *sk\_msgRegister()*, and the LLC is supposed to be connected to a node but is not connected to the node's active .

#### More on SK\_LINK\_UP and SK\_LINK\_DOWN

- Registering for *ServerStatusChange* will result in an SK\_LINK\_UP or SK\_LINK\_DOWN for each node controlled by the LLC. If an SK\_LINK\_UP is sent, it will be followed by an SK\_SSC\_UPDATE with the last poll from the active .
- Performing an *AddLLCNode* will result in an SK\_LINK\_UP or SK\_LINK\_DOWN for the specified node if the LLC is already controlling the node. If an SK\_LINK\_UP is sent, it will be followed by an SK\_SSC\_UPDATE with the last poll from the active , if the LLC is currently connected to the in the active state.

- SK\_PM\_CHANGE, SK\_SOCKET\_CHANGE, SK\_LINK\_UP and SK\_LINK\_DOWN are generated to indicate a change in state.
- SK\_NSQ\_CHANGE or SK\_NSR\_CHANGE are generated upon arrival of *NodeStatusQueryAck* or *NodeStatusReport* from the CSP.

**Arguments** The following table indicates what arguments are valid for a specific message trigger:

| MessageTrigger                | Argument         | Description                                                                                                                                  |
|-------------------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| SK_PM_CHANGE or SK_SSC_UPDATE | PhysicalNode     | Represents the requested Node ID                                                                                                             |
|                               | LogicalNode      | Represents the current Node ID as reported by the CSP in <i>PollMessage</i>                                                                  |
|                               | SocketStatus     | 1 always. Socket must be connected for this indication to occur.                                                                             |
|                               | Status           | Status from <i>PollMessage</i>                                                                                                               |
|                               | SystemType       | System Type(Poll Source) from <i>PollMessage</i>                                                                                             |
|                               | MatrixSide       | Matrix Controller ID from <i>PollMessage</i>                                                                                                 |
|                               | MatrixState      | Matrix State(Card State) from <i>PollMessage</i>                                                                                             |
|                               | AdjMatrixState   | Adjacent Card State from <i>PollMessage</i>                                                                                                  |
|                               | StatusBits       | Card Status from <i>PollMessage</i>                                                                                                          |
|                               | CSP Port         | Double Byte after Multi Host Connection Status Byte 2 in <i>PollMessage</i>                                                                  |
|                               | UpdatedFieldBits | Bit mask indicating which fields in the poll were updated. See table below for details of the meaning of the bits. Only set for SK_PM_CHANGE |
| SK_LINK_UP or SK_LINK_DOWN    | PhysicalNode     | Requested Node ID                                                                                                                            |
|                               | LogicalNode      | Requested Node ID                                                                                                                            |

**Constants** The following table contains information for the field UpdatedFieldBits. You can combine any number of settings in this bit mask:

| <b>Constants</b>         | <b>Changed Argument in <i>Server StatusChange</i> message</b> |
|--------------------------|---------------------------------------------------------------|
| SK_STATUS_CHANGE         | Status                                                        |
| SK_SYSTEMTYPE_CHANGE     | SystemType                                                    |
| SK_MATRIXSIDE_CHANGE     | MatrixSide                                                    |
| SK_MATRIXSTATE_CHANGE    | MatrixState                                                   |
| SK_ADJMATRIXSTATE_CHANGE | AdjMatrixState                                                |
| SK_STATUSBITS_CHANGE     | StatusBits                                                    |
| SK_LOGICALNODE_CHANGE    | LogicalNode                                                   |

## Service State Configure 0x000A

---

**SwitchKit Name** ServiceStateConfig

**Type** EXS API and SwitchKit API message

**Description** This message allows the host to bring an entity (a card, span, channel, range of channels, DSP SIMM, or SS7-controlled circuit) in and out of service. On the DSP Series 2 card, this message must use AIB 0x22 to take an individual DSP chip in and out of service.

- A card is automatically brought into service when the system is powered up. The host does not have to bring a card into service unless it has previously taken the card out of service using this message.
- The DS3 framer is automatically brought into service when the DS3 card is brought into service. Once in service, DS3 status changes are reported to the host in the *Alarm* messages (0x00B9). If the DS3 circuit is not ready for operation, the host can disable DS3 alarms by placing the DS3 framer out of service. To do this, have the host send a *Service State Configure* message with the DS3 Offset AIB (0x32) and an action of 0x0F (Take Out of Service).

If the host does take the DS3 Framer Out of Service, it is the host's responsibility to bring it back in service. If the host does not bring the DS3 Framer back in service, the CSP will send a NACK 0x005A (DS3 Out of Service) when it receives the *Service State Configure* message to Brings Span In Service.

- The DS3 Offset AIB must always be 0.
- For LAPD Super Rate, this message must address the first D channel (DS0). The other D channels in the Super Rate D channel do not need to be addressed in *Service State Configure*.
- You cannot use *Service State Configure* to take virtual cards out-of-service.

**Sent by** Host

**Example Message (Socket Log Output)** The following example message (socket log output for SwitchKit) takes channels 0x01 through 0x05 on span 0x01 out of service.

```
00 13 00 0A 00 00 FF 01 02 0D 03 00 01 01 0D 03 00 01 05 0F 00
```

**Configuration**

```
ServiceStateConfig (
 Node = Integer,
 Range = StartSpan:StartChan - EndSpan:EndChan,
 Span = Integer,
 Slot = Integer,
 SIMM = Integer,
```

```
StackID = Integer,
LinkID = Integer,
Ring = Integer,
V5ID = Integer,
DS3 = Integer,
Action = Integer,
ForcedFlag = Integer);
```

**C Structure**

```
typedef struct {
 UBYTE AddrInfo[30];
 UBYTE Action;
 UBYTE ForcedFlag;
} XL_ServiceStateConfig;
```

**C++ Class**

```
class XLC_ServiceStateConfig : public
 XLC_ChanRangeMessage {
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 XBYTE getStartSpan() const;
 void setStartSpan(XBYTE x);
 UBYTE getStartChannel() const;
 void setStartChannel(UBYTE x);
 XBYTE getEndSpan() const;
 void setEndSpan(XBYTE x);
 UBYTE getEndChannel() const;
 void setEndChannel(UBYTE x);
 UBYTE getDSPChip() const;
 void setDSPChip(UBYTE x);
 UBYTE getDSPSlot() const;
 void setDSPSlot(UBYTE x);
 UBYTE getDSPSIMM() const;
 void setDSPSIMM(UBYTE x);
 UBYTE getSlot() const;
 void setSlot(UBYTE x);
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 UBYTE getLni() const;
 void setLni(UBYTE x);
 UBYTE getSIMM() const;
 void setSIMM(UBYTE x);
 UBYTE getDS3() const;
 void setDS3(UBYTE x);
 XBYTE getSpan() const;
 void setSpan(XBYTE x);
 XBYTE getV5ID() const;
 void setV5ID(XBYTE x);
 UBYTE getAction() const;
 void setAction(UBYTE x);
 UBYTE getForcedFlag() const;
 void setForcedFlag(UBYTE x);
};
```

**EXS API Hex Format**

| MESSAGE (White) |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | RESPONSE (Gray) |                                              |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|----------------------------------------------|
| Byte            | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Byte            | Field Description                            |
| 0               | Frame (0xFE)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 0               | Frame (0xFE)                                 |

## Invalid Responses

**NOTE:** These invalid responses apply to the V5 ID address type only

- 0x01-The host could be attempting to bring the V5 interface in service or out of service when the V5 Interface ID (4 bytes) has not been configured. The host could be attempting to bring the V5 interface in service or out of service when the V5 ID is not configured.
- 0x04- The host could be attempting to bring the V5 interface in service when the V5 Variant ID has not been configured for that interface.
- 0x07-The host could be attempting to bring the V5 interface in service when no user ports are configured for the V5 ID.
- 0x0A-The host could be attempting to bring the V5 interface in service when no C Channels are assigned to this V5 ID.
- 0x0B-The host was attempting to bring a V5 interface in service when a C Channel was found on an unconfigured link.
- 0x0DRESERVED  
0x0ERESERVED  
0x0FRESERVED

## Notes:

- 1 When a DS3 is taken out of service, the CSP automatically takes all spans and channels on the DS3 out of service. When the DS3 is brought back in service, the spans and channels are *not* automatically brought back in service. You must manually bring the spans and channels in service. A DS3 must be in service before any spans can be brought in service. The CSP returns a status of *DS3 Out of Service* (0x5A) if you attempt to bring a span in service first.
- 2 When bringing a card in service that was previously out of service, the host must wait for a *Card Status Report* message on the appropriate slot before considering the card in service.
- 3 When a span is taken out of service, all channels on the span are automatically taken out of service by the CSP. When the span is brought back in service using this message, the channels are not automatically brought back in service. You must send this message again to bring the channels back into service.
- 4 The host should not consider a channel in service upon receiving the Response to this message. The host must

receive a *DS0 Status Change* message with status of “In Service” before considering the channel in service.

- 5 If you are using E1 Channel 30 for purposes other than CAS (for example, CCS), you cannot include it in a range with other channels. Instead, you must bring E1 Channel 30 into service with a single separate *Service State Configure* message. Be sure that both the starting and ending spans and channels are set to the span and channel 30.
- 6 If you take an E1 PPL channel out of service using this message, the host receives the following:
  - A *DS0 Status Change* message (0x42) that has a *Channel Status* field value of 0x01 (Out of Service).
  - A *DS0 Status Change* message (0x42) that has a *Channel Status* field value of 0x00 (Purge) and a *Purge Reason* field value of 0x74 (Disabled While Non-dormant). The system sends this second message to the host as a result of meeting certain criteria but does not actually perform a purge. You can ignore this second message.

## SNMP Configure 0x0092

| <b>Description</b>    | <p>This message is used to configure the detection of a Carrier Group Alarm (CGA), such as an AIS (Alarm Indication Signal) or LOF (Loss of Frame). The “CGA Detected” validation timer determines how long a CGA alarm must be detected before the CSP informs the host with an <i>Alarm</i> message. The default is 2.5 seconds. The host will also receive a <i>DS0 Status Change</i> message of “Out Of Service” for the channels on the span.</p> <p>The “CGA Cleared” validation timer is initiated after a CGA alarm has been detected and then clears. It determines how long the CSP must go without detecting a CGA alarm before informing the host with an <i>Alarm Cleared</i> message. The default is 12 seconds. The host will also receive a <i>DS0 Status Change</i> message of “In Service” for the channels on the span.</p> |

| <b>Description</b>    | <p>This message is used to query the values of the CGA detected and cleared validation timers</p> <p>The “CGA Detected” validation timer determines how long a CGA alarm must be detected before the CSP informs the host with an <i>Alarm</i> message. The default is 2.5 seconds. The host will also receive a <i>DS0 Status Change</i> message of “Out Of Service” for the channels on the span.</p> <p>The “CGA Cleared” validation timer is initiated after a CGA alarm has been detected and then clears. It determines how long the CSP must go without detecting a CGA alarm before informing the host with an <i>Alarm Cleared</i> message. The default is 12 seconds. The host will also receive a <i>DS0 Status Change</i> message of “In Service” for the channels on the span.</p> |

| <b>Type</b>           | EXS API and SwitchKit API message                                                                                                                                                                                                                                                                  |
| <b>Description</b>    | <p>This message may be used by the host to obtain information about the state of an in-service T1 or E1 span. It resets bipolar violations and frame error contents.</p> <p>For the SS7 Multi-Protocol I/O card, the positive acknowledgement to this query contains zeros in the data fields.</p> |
| <b>Sent by</b>        | Host                                                                                                                                                                                                                                                                                               |

### SwitchKit Code C Structure

```
typedef struct {
 unsigned short Status;

| <b>Description</b>    | <p>This message allows the host to define an association between channels on logical spans and SS7 CICs. CICs in a CIC group must be on the same span and in contiguous timeslots. You can also use this message to deconfigure CIC group.</p> <p>You must use this message for one CIC group at a time. You cannot use this message on multiple CIC groups.</p> <p>To deconfigure a CIC group, use this message but substitute the value 0xFFFFFFFF for the DPC. If the CICs are in-service, the host receives DS0 status messages for the CICs with a status of out-of-service.</p> |
| <b>Sent by</b>        | Host                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## CIC Assignment over E1

For CIC assignments over E1, the base channel refers to the Cantata channel shown in the table below. The number of CICs defines the CIC range using the contiguous timeslots as the range. In the example table below there is no signaling link on the span. There is a base CIC of 0x00 and 31 CICs that can be configured as one group. If there is a signaling link on the span on a timeslot other than timeslot 1 (Cantata channel 0x00) then the CIC configure has to be split in two groups.

Note that this table is an example and reflects one way to assign CICs over E1.

| <b>Cantata Channel</b> | <b>Timeslot</b> | <b>Full-span<br/>No SS7 Link</b> | <b>Last Channel<br/>Used as SS7<br/>Link</b> | <b>First Channel<br/>Used as SS7<br/>Link</b> |
|------------------------|-----------------|----------------------------------|----------------------------------------------|-----------------------------------------------|

## Call Control User Part

## Japanese ISUP CIC Mapping Options

If you select ISUP/Japanese ISUP CIC Mapping (0x02), you must map CICs according to one of the following three options:

- Full span
- Last channel not used as CIC
- First channel not used as CIC

The values of the channels based for each option above are shown in the table below.

| CSP Channel | Timeslot | Full-span No SS7 Link  | Last Channel Used as SS7 Link     | First Channel Used as SS7 Link    |
|-------------|----------|------------------------|-----------------------------------|-----------------------------------|
| 31          | 0        | Frame Alignment Signal |                                   |                                   |
| 0           | 1        | Base CIC + 0           | Base CIC + 0                      | Not used as CIC (may be SS7 link) |
| 1           | 2        | Base CIC + 6           | Base CIC + 6                      | Base CIC + 5                      |
| 2           | 3        | Base CIC + 12          | Base CIC + 12                     | Base CIC + 11                     |
| 3           | 4        | Base CIC + 18          | Base CIC + 18                     | Base CIC + 17                     |
| 4           | 5        | Base CIC + 24          | Base CIC + 24                     | Base CIC + 23                     |

### Response Data

The meaning of these fields depends upon the value of the *Entity* field in the message. The following value can be received:

0x7F Software module still locked.

This value is returned when attempting to configure a locked module for which no product license has been downloaded.

0xFD Node ID Not Configured

This response is a result of an SS7 server node configuration. Assignment of spans failed because node is not yet assigned. When sending the *SS7 CIC Configure* message (0x006A) over the EXNET ring, this response value indicates the Ethernet connection is not available to the SS7 I/O card and you should check the connection.

## SS7 CIC Query 0x0067

---

| <b>Sent by</b>        | Host                                                  |

### SwitchKit Code C Structure

```
typedef struct {
 UBYTE StackID;
 int DPC;
 unsigned short BaseCIC;
 UBYTE NumCICs;
 UBYTE CallControlUserPart;
} XL_SS7CICQuery;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE StackID;
 unsigned short BaseCICNumber;
 unsigned short BaseCICSpan;
 UBYTE BaseCICChannel;
 UBYTE NumCICs;
 int DPC;
 UBYTE Data[217];
} XL_SS7CICQueryAck;
```

### C++ Class

```
class XLC_SS7CICQuery : public XLC_OutboundMessage {
public:
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 int getDPC() const;
 void setDPC(int x);
 unsigned short getBaseCIC() const;
 void setBaseCIC(unsigned short x);
 UBYTE getNumCICs() const;
 void setNumCICs(UBYTE x);
 UBYTE getCallControlUserPart() const;
 void setCallControlUserPart(UBYTE x);
};
```

### C++ Class Response

```
class XLC_SS7CICQueryAck : public XLC_AcknowledgeMessage
{
public:
 unsigned short getStatus() const;
```

```

void setStatus(unsigned short x);
UBYTE getStackID() const;
void setStackID(UBYTE x);
unsigned short getBaseCICNumber() const;
void setBaseCICNumber(unsigned short x);
unsigned short getBaseCICSpan() const;
void setBaseCICSpan(unsigned short x);
UBYTE getBaseCICChannel() const;
void setBaseCICChannel(UBYTE x);
UBYTE getNumCICs() const;
void setNumCICs(UBYTE x);
int getDPC() const;
void setDPC(int x);
const UBYTE *getData() const;
UBYTE *getData();
void setData(UBYTE *x);
};

```

**EXS API Hex Format**

**NOTE:** The five fields listed in the Response (Gray) starting with (CIC n Status and ending with CIC n PCM Encoding Format) are repeated for each CIC. The SS7 CIC Group address type contains the number of CICs.

| <b>Type</b>           | EXS API and SwitchKit API message                                                                 |
| <b>Description:</b>   | This message allows the host to configure CLLI (Common Language Location Identifier) information. |
| <b>Sent by:</b>       | Host                                                                                              |

### SwitchKit Code Configuration

```
SS7CLLIConfig (
 Node = integer,
 StackID = integer,
 BaseCICNumber = integer,
 BaseCICSpan = integer,
 BaseCICChannel = integer,
 NumCICs = integer,
 DataFormat = integer,
 TLVCount = integer,
 TLVData= byte array);
```

### C Structure

```
typedef struct {
 UBYTE StackID;
 unsigned short BaseCICNumber;
 unsigned short BaseCICSpan;
 UBYTE BaseCICChannel;
 UBYTE NumCICs;
 UBYTE DataFormat;
 UBYTE TLVCount;
 UBYTE TLVData[221];
} XL_SS7CLLIConfig;
```

### C++ Class

```
class XLC_SS7CLLIConfig : public XLC_OutboundMessage {
public:
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 unsigned short getBaseCICNumber() const;
 void setBaseCICNumber(unsigned short x);
 unsigned short getBaseCICSpan() const;
 void setBaseCICSpan(unsigned short x);
 UBYTE getBaseCICChannel() const;
 void setBaseCICChannel(UBYTE x);
 UBYTE getNumCICs() const;
 void setNumCICs(UBYTE x);
 UBYTE getDataFormat() const;
 void setDataFormat(UBYTE x);
 UBYTE getTLVCount() const;
 void setTLVCount(UBYTE x);
```

```

const UBYTE *getTLVData() const;
UBYTE *getTLVData();
void setTLVData(UBYTE *x);
};

```

| <b>Description</b>    | <p>Use this message to add, remove or modify the format of an ISUP message in the ISUP Message Format table.</p> <p>Each of these configuration messages is used to format outgoing ISUP messages and to interpret incoming ISUP messages.</p> <p>For each message, there can be a maximum of eight Mandatory Fixed Parameters, eight Mandatory Variable Parameters, and 42 Optional Parameters.</p> <p>Use the <i>SS7 ISUP Message Query</i> message to retrieve the currently configured format of an ISUP message.</p> <p>Modifying the format of an ISUP message may also require modification of its PPL Configuration Bytes.</p> |

**SwitchKit Code** **Configuration**

```
SS7ISUPMessageFormatConfig (
 Node = integer,
 StackID = integer,
 ISUPMessageIndex = integer,
 ISUPMessageID = integer,
 ISUPMessagePriority = integer,
 NumMFPs = integer,
 Data = byte array);
```

**C Structure**

```
typedef struct {
 UBYTE StackID;
 UBYTE ISUPMessageIndex;
 UBYTE ISUPMessageID;
 UBYTE ISUPMessagePriority;
 UBYTE NumMFPs;
 UBYTE Data[219];
} XL_SS7ISUPMessageFormatConfig;
```

**C++ Class**

```
class XLC_SS7ISUPMessageFormatConfig : public
 XLC_OutboundMessage {
public:
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 UBYTE getISUPMessageIndex() const;
 void setISUPMessageIndex(UBYTE x);
 UBYTE getISUPMessageID() const;
```

```

void setISUPMessageID(UBYTE x);
UBYTE getISUPMessagePriority() const;
void setISUPMessagePriority(UBYTE x);
UBYTE getNumMFPs() const;
void setNumMFPs(UBYTE x);
const UBYTE *getData() const;
UBYTE *getData();
void setData(UBYTE *x);
};

```

**ISUP Message Index**

This field specifies an index that is maintained for internal use by the CSP into the ISUP Message Format table for the specified ISUP message. The valid entries for this field are in numeric order.

| Message | Index |  | Message | Index |  | Message | Index |
|---------|-------|--|---------|-------|--|---------|-------|
| IAM     | 0x00  |  | LPA     | 0x14  |  | CVT     | 0x28  |
| ACM     | 0x01  |  | CFN     | 0x15  |  | CVR     | 0x29  |
| ANM     | 0x02  |  | UCIC    | 0x16  |  | CRM     | 0x2A  |
| CON     | 0x03  |  | CQM     | 0x17  |  | CRA     | 0x2B  |
| REL     | 0x04  |  | CQR     | 0x18  |  | UPT     | 0x2C  |
| RLC     | 0x05  |  | FAR     | 0x19  |  | UPA     | 0x2D  |
| CPG     | 0x06  |  | FAA     | 0x1A  |  | EXM     | 0x2E  |
| BLO     | 0x07  |  | FRJ     | 0x1B  |  | MPM     | 0x4F  |
| BLA     | 0x08  |  | USR     | 0x1C  |  | OPR     | 0x50  |
| UBL     | 0x09  |  | FAC     | 0x1D  |  | CCL     | 0x51  |
| UBA     | 0x0A  |  | PAM     | 0x1E  |  | DRS     | 0x52  |
| RSC     | 0x0B  |  | NRM     | 0x1F  |  | FOT     | 0x53  |
| CGB     | 0x0C  |  | CRG     | 0x20  |  | OLM     | 0x54  |
| CGBA    | 0x0D  |  | IDR     | 0x21  |  | SGM     | 0x55  |
| CGU     | 0x0E  |  | IRS     | 0x22  |  | CMR     | 0x56  |
| CGUA    | 0x0F  |  | INR     | 0x23  |  | CMC     | 0x57  |
| GRS     | 0x10  |  | INF     | 0x24  |  | CMRJ    | 0x58  |
| GRA     | 0x11  |  | SUS     | 0x25  |  | LOP     | 0x59  |
| CCR     | 0x12  |  | RES     | 0x26  |  | APM     | 0x5A  |
| COT     | 0x13  |  | SAM     | 0x27  |  | PRI     | 0x5B  |

Index values 0x2F-0x4E are user-defined for the ISUP message format table:

| Message     | Index |  | Message     | Index |  | Message     | Index |
|-------------|-------|--|-------------|-------|--|-------------|-------|
| Message #1  | 0x2F  |  | Message #14 | 0x3C  |  | Message #27 | 0x49  |
| Message #2  | 0x30  |  | Message #15 | 0x3D  |  | Message #28 | 0x4A  |
| Message #3  | 0x31  |  | Message #16 | 0x3E  |  | Message #29 | 0x4B  |
| Message #4  | 0x32  |  | Message #17 | 0x3F  |  | Message #30 | 0x4C  |
| Message #5  | 0x33  |  | Message #18 | 0x40  |  | Message #31 | 0x4D  |
| Message #6  | 0x34  |  | Message #19 | 0x41  |  | Message #32 | 0x4E  |
| Message #7  | 0x35  |  | Message #20 | 0x42  |  |             |       |
| Message #8  | 0x36  |  | Message #21 | 0x43  |  |             |       |
| Message #9  | 0x37  |  | Message #22 | 0x44  |  |             |       |
| Message #10 | 0x38  |  | Message #23 | 0x45  |  |             |       |
| Message #11 | 0x39  |  | Message #24 | 0x46  |  |             |       |
| Message #12 | 0x3A  |  | Message #25 | 0x47  |  |             |       |
| Message #13 | 0x3B  |  | Message #26 | 0x48  |  |             |       |

**ISUP Message ID**

This field specifies the ISUP Message ID for the specified ISUP message from the ISUP Message Format table. Valid entries for this field are listed by ISUP message name:

| Message | ID   |  | Message | ID   |  | Message | ID   |
|---------|------|--|---------|------|--|---------|------|
| ACM     | 0x06 |  | CRM     | 0xEA |  | OLM     | 0x30 |
| ANM     | 0x09 |  | CVR     | 0xEB |  | OPR     | 0xFE |
| APM     | 0x41 |  | CVT     | 0xEC |  | PAM     | 0x28 |
| BLA     | 0x15 |  | DRS     | 0x27 |  | PRI     | 0x42 |
| BLO     | 0x13 |  | EXM     | 0xED |  | REL     | 0x0C |
| CCL     | 0xFC |  | FAA     | 0x20 |  | RES     | 0x0E |
| CFN     | 0x2F |  | FAC     | 0x33 |  | RLC     | 0x10 |
| CGB     | 0x18 |  | FAR     | 0x1F |  | RSC     | 0x12 |
| CGBA    | 0x1A |  | FOT     | 0x08 |  | SAM     | 0x02 |
| CGU     | 0x19 |  | FRJ     | 0x21 |  | SGM     | 0x38 |

| CRA     | 0xE9 |  | MPM     | 0xFD |  |         |      |
| CRG     | 0x31 |  | NRM     | 0x32 |  |         |      |

**Repeatable Optional  
Parameters/Optional  
Parameters Allowed**

This field informs ISUP whether or not to look for or insert the optional parameters pointer octet in the ISUP message.

Some messages allow optional parameters, even though optional parameters are not defined (for example, the ITU Q.767 Release Complete (RLC) message).

- Optional parameters are required for the incoming message when you set the value of the *Optional Parameters Allowed* field to **0x01**. This is the default value. When you set this value to **0x01** and optional parameters are included in the message, the CSP automatically inserts the *End of Optional Parameters* octet. If the optional parameter pointer is missing in the incoming message, the CFN (Confusion message) will be returned.
- The maximum number of Optional Parameters is 52.
- For no optional parameters, set the value of the *Optional Parameters Allowed* field to **0x00** and the value of the *Number of Optional Parameters* field to **0x00**. You must complete this step to support the pre-1995 ANSI format for the Group Reset (GRS) and Group Reset Acknowledgement (GRA) messages.

**Example:** API message:

```
00 1f 00 6b 00 00 ff 00 01 08 01 00 10 17 00 00 01 16 01 01 01 00
00 02 4e 21 00 01 01 4e 22 00 01 01
```

```
00 1f 00 6b 00 00 ff 00 01 08 01 00 11 29 00 00 01 16 01 04 00 00
02 4e 21 00 01 01 4e 22 00 01 01
```

**Example:** SwitchKit API:

```

```

- For Repeatable Optional Parameters, set the value of this field to the number of repeated optional parameters.

| MSB                                                         | LSB                                    |
|-------------------------------------------------------------|----------------------------------------|
| Bits 7-1 Number of Repeatable Optional Parameters Indicator | Bit 0<br>Optional Parameters Indicator |

## Options for Optional Parameters Allowed Indicator

- 0 Optional Parameters Not Allowed
- 1 Optional Parameters Allowed

## Options for Number of Repeatable Optional Parameters

- 0 No Repeatable Optional Parameters
- 1 -127 Indicate the number Repeatable Optional Parameters

**Maximum Length**

A value of 0x00 for the maximum length fields indicates that no validation is performed for the maximum length of the parameter.

## SS7 ISUP Message Query 0x0068

**ISUP Message Index**

This field specifies an index that is maintained for internal use by the CSP into the ISUP Message Format table for the specified ISUP message. The valid entries for this field are in numeric order.

| Message | Index | Message | Index | Message | Index |
|---------|-------|---------|-------|---------|-------|

### ISUP Message ID

This field specifies the ISUP Message ID for the specified ISUP message from the ISUP Message Format table. Valid entries for this field are listed by ISUP message name:

| Message | ID   | Message | ID   | Message | ID   |
|---------|------|---------|------|---------|------|
| ACM     | 0x06 | CRM     | 0xEA | OLM     | 0x30 |
| ANM     | 0x09 | CVR     | 0xEB | OPR     | 0xFE |
| APM     | 0x41 | CVT     | 0xEC | PAM     | 0x28 |
| BLA     | 0x15 | DRS     | 0x27 | PRI     | 0x42 |
| BLO     | 0x13 | EXM     | 0xED | REL     | 0x0C |
| CCL     | 0xFC | FAA     | 0x20 | RES     | 0x0E |
| CFN     | 0x2F | FAC     | 0x33 | RLC     | 0x10 |
| CGB     | 0x18 | FAR     | 0x1F | RSC     | 0x12 |
| CGBA    | 0x1A | FOT     | 0x08 | SAM     | 0x02 |
| CGU     | 0x19 | FRJ     | 0x21 | SGM     | 0x38 |
| CGUA    | 0x1B | GRA     | 0x29 | SUS     | 0x0D |
| CON     | 0x07 | GRS     | 0x17 | UBA     | 0x16 |

| Message | ID   | Message | ID   | Message | ID   |
|---------|------|---------|------|---------|------|
| CMC     | 0x49 | IAM     | 0x01 | UBL     | 0x14 |
| CMRJ    | 0x4A | IDR     | 0x36 | UCIC    | 0x2E |
| CMR     | 0x4B | INF     | 0x04 | UPA     | 0x35 |

| CRG     | 0x31 | NRM     | 0x32 |         |      |

### Repeatable Optional Parameters/Optional Parameters Allowed

This field informs ISUP whether or not to look for or insert the optional parameters pointer octet in the ISUP message.

Some messages allow optional parameters, even though optional parameters are not defined (for example, the ITU Q.767 Release Complete (RLC) message).

- To include optional parameters, set the value of the *Optional Parameters Allowed* field to **0x01**.  
When you set this value to 0x01 and optional parameters are included in the message, the CSP automatically inserts the *End of Optional Parameters* octet.
- For no optional parameters, set the value of the *Optional Parameters Allowed* field to **0x00** and the value of the *Number of Optional Parameters* field to **0x00**.
- For Repeatable Optional Parameters, set the value of this field to the number of repeated optional parameters.

| MSB                                                         | LSB                                 |
|-------------------------------------------------------------|-------------------------------------|
| Bits 7-1 Number of Repeatable Optional Parameters Indicator | Bit 0 Optional Parameters Indicator |

Options for Optional Parameters Allowed Indicator

0 Optional Parameters Not Allowed

1 Optional Parameters Allowed

Options for Number of Repeatable Optional Parameters

0 No Repeatable Optional Parameters

1 -127 Indicate the number Repeatable Optional Parameters

### Maximum Length

A value of 0x00 for the maximum length fields indicates that no validation is performed for the maximum length of the parameter.

## SS7 SCCP/TCAP Configure 0x0077

|                       |                                                              |
|-----------------------|--------------------------------------------------------------|
| <b>SwitchKit Name</b> | SS7SCCPTCAPConfig                                            |
| <b>Type</b>           | EXS API and SwitchKit API message                            |
| <b>Description</b>    | This message is sent to configure options for SS7 SCCP/TCAP. |

### **For SwitchKit**

Those options include:

- Local SSN
- Adjacent Translator
- Other Concerned Point Code
- SCCP Default Parameter Table
- SSN Default Parameter Table
- TCAP Object Syntax Descriptor (OSD)
- Network DPC/SSN
- SCCP/TCAP host configuration

In a SwitchKit environment, this message must be sent by an application or by SwitchManager with ConfigType = 1, Data = [2:1] specifying “SCCP route message to TCAP”. Without sending this message first and receiving a positive acknowledgment it is impossible to add or specify a node as a TCAP node.

#### 0x06 TCAP OSD

Data[0] Option  
0x03 Modify an existing TCAP object.

Data[1-2] TCAP object parameter ID  
(See the *Developer's Guide: Common Channel Signaling for SCCP/TCAP Parameter Information*.)

Data[3-4] TCAP identifier

Data[5] Syntax update flag/Object data type (always 0x00)

0x00 Do not update the object syntax /other Object data type

Data[6+] Object syntax description follows if Data[5] is not 0x00.

#### 0x07 Network DPC/SSN

Data[0] Local Subsystem Number

Data[1] Option  
0x01 Add Network DPC/SSN  
0x02 Delete Network DPC/SSN

Data[2-5] DPC

Data[6] Remote SSN Number

#### 0x08 SCCP/TCAP host configuration

Data[0] Subsystem Number

Data[1] Option  
0x01 Add a host  
0x02 Delete a host

Data[2] Local/Matrix host  
0xFE Local host  
0xFF Matrix host

Data[3] Host Port ID (0-5)

Port IDs 0-5 correspond to Ports 0x3142-0x3147.

NOTE: Only one host can be configured for each stack/subsystem. The default host is the matrix primary host. Also, an SS7 card supports only one port: 0x3142. Note however that it is possible to have an additional direct connection between the second host and the TCAP on the SS7 card using the CCS I/O card.

## SS7 SCCP/TCAP Query 0x0078

---

|                       |                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------|
| <b>SwitchKit Name</b> | SS7SCCPTCAPQuery                                                                       |
| <b>Type</b>           | EXS API and SwitchKit API message                                                      |
| <b>Description</b>    | This message is sent to configure query information about SS7 SCCP/TCAP configuration. |
| <b>Sent by</b>        | Host                                                                                   |

### SwitchKit Code C Structure

```
typedef struct {
 UBYTE StackID;
 UBYTE reserved18[29];
 UBYTE QueryType;
 UBYTE Data[222];
} XL_SS7SCCPTCAPQuery;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE StackID;
 UBYTE QueryType;
 UBYTE Data[220];
} XL_SS7SCCPTCAPQueryAck;
```

### C++ Class

```
class XLC_SS7SCCPTCAPQuery : public XLC_OutboundMessage {
public:
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 UBYTE getQueryType() const;
 void setQueryType(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

### C++ Class Response

```
class XLC_SS7SCCPTCAPQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 UBYTE getQueryType() const;
 void setQueryType(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**Overview of message** The following table provides an overview of this message. The table following it, provides the detail for each byte.

| MESSAGE (White) |                         | RESPONSE (Gray) |                       |
|-----------------|-------------------------|-----------------|-----------------------|
| Byte            | Field Description       | Byte            | Field Description     |

#### 0x02 SCCP/TCAP Default Parameter Table

Data[0-1] Parameter Type

Data[2-3] Parameter Length

Data[4+] Parameter Value

Refer to the *Developer's Guide: Common Channel Signaling* for Parameter Information.

#### 0x03 SSN Default Parameter Table

Data[0] Subsystem Number

Data[1-2] Parameter Type

Data[3-4] Parameter Length

Data[5+] Parameter Value

Refer to the *Developer's Guide: Common Channel Signaling* for Parameter Information.

#### 0x04 TCAP OSD

Data[0-1] TCAP object parameter ID.

(Refer to the *Developer's Guide: Common Channel Signaling* for TCAP OSD Parameter IDs.)

Data[2-3] TCAP identifier

Data[4] Object data type (always 0x00)

0x00 Information not available/ other Object data type

Data[5+] Object syntax description follows if Data[4] is not 0x00.

#### 0x05 TCAP Active Transactions

Data[0] Subsystem Number

Data[1-4] Dialog ID (4 bytes)

Data[5-8] Transaction Originating Transaction ID (4 bytes)

Data[9-12] Transaction Responding Transaction ID (4 bytes)

Data[13] Transaction State

#### ANSI

The following *Transaction State* values apply for ANSI:

0x00 Idle

0x01 Query Without Permission package has been sent

0x02 Query With Permission package has been sent

0x03 Query Without Permission package has been received

0x04 Query With Permission package has been received

0x05 Conversation With Permission package has been received

0x06 Conversation Without Permission package has been received

0x07 Conversation Without Permission package has been sent

0x08 Conversation With Permission package has been sent

## ITU

The following *Transaction State* values apply for ITU:

- 0x00 Idle
- 0x01 Initiation Received
- 0x02 Initiation Sent
- 0x03 Active

The following bytes are the stored CGPA for this transaction:

- Data[14-15] CGPA Parameter Type
- Data[16-17] Parameter Length
- Data[18+] Parameter Value

The following bytes are the stored CGPA for this transaction:

- Data[:] CDPA Parameter Type
- Data[:] Parameter Length
- Data[+] Parameter Value
- Data[:]:

Refer to the *Developer's Guide: Common Channel Signaling* for Parameter Information.

Data[:]Reserved

### 0x06 TCAP Active Operations

- Data[0] Subsystem Number
- Data[1-5]Dialog ID (4 bytes)
- Data[6-7]Operation Invoke ID
- Data[8-9]Operation Correlation ID

The MSB is always 0x00 unless the Correlation ID is not available, in which case it is 0xFF)

- Data[10] Operation State

## ANSI

The following *Operation State* values apply for ANSI:

- 0x00 Idle The operation is not initiated
- 0x01 Operation is Pending The state machine is waiting for an incoming component from the network
- 0x02 Operation is in Progress The state machine is expecting the host to send a responding component
- 0x03 Operation Local Pending All components required for this operation are stored in TCAP.  
A Dialog primitive must be sent to send the components to the network.  
In this state, any component received for this operation from the network or the host will be rejected.

## ITU

The following *Operation State* values apply for ITU:

- 0x00 Idle
- 0x01 Operation Sent Class 1
- 0x02 Wait for Reject
- 0x03 Operation Sent Class 2
- 0x04 Operation Sent Class 3
- 0x05 Operation Sent Class 4
- Data[9-12]Reserved

## 0x0B Number of active dialogs and invocations

Data[0-3] number of active dialogs

Data[4-7] number of active invocations

Data[8-11] next available dialog ID stack will use for the next incoming new dialog

## 0x0C TLV Format Configuration Contents

0x09D1 Global Title Group Query Response

0x09D2 Global Title Entry Query Response

## SS7 Signaling Link Configure 0x005E

| <b>SwitchKit Name</b> | SS7SignalingLinkQuery                                 |
| <b>Type</b>           | EXS API and SwitchKit API message                     |
| <b>Description</b>    | This message queries information on a signaling link. |
| <b>Sent by</b>        | Host                                                  |

### SwitchKit Code C Structure

```
typedef struct {
 UBYTE StackID;
 UBYTE LinkSetID;
} XL_SS7SignalingLinkQuery;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE StackID;
 UBYTE LinkSetID;
 UBYTE NumLinks;
 UBYTE Data[220];
} XL_SS7SignalingLinkQueryAck;
```

### C++ Class

```
class XLC_SS7SignalingLinkQuery : public
 XLC_OutboundMessage {
public:
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 UBYTE getLinkSetID() const;
 void setLinkSetID(UBYTE x);
};
```

### C++ Class Response

```
class XLC_SS7SignalingLinkQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 UBYTE getLinkSetID() const;
 void setLinkSetID(UBYTE x);
 UBYTE getNumLinks() const;
 void setNumLinks(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**EXS API Hex Format**

| <b>Description</b>                                       | <p>This message allows the host to define and subsequently deconfigure a signaling link set, which is a load-sharing collection of signaling links connected to an adjacent signaling node. The link set and stack must be configured before the signaling links.</p> <p>You can also set this message to deconfigure a link set.</p> |
| <b>Example Message (Socket Log Output for SwitchKit)</b> | <p>The following example message defines a signaling link set with an OPC for a signaling stack that uses 24-bit point codes (ANSI).</p>                                                                                                                                                                                              |

# SS7 Signaling Link Set Query 0x0064

---

|                        |                                                                            |
|------------------------|----------------------------------------------------------------------------|
| <b>SwitchKit Name'</b> | SS7SignalingLinkSetQuery                                                   |
| <b>Type</b>            | EXS API and SwitchKit API message                                          |
| <b>Description</b>     | This message allows the host to query information on a signaling link set. |

**NOTE:** Every point code in API messages will always be 4 bytes long with the first byte MSB as zero. See *Signaling System 7* in the *API Developer's Guide: CCS* for an explanation of how to convert the 4 bytes for APC into ITU and ANSI point codes.

**Sent by** Host

## SwitchKit Code C Structure

```
typedef struct {
 UBYTE StackID;
} XL_SS7SignalingLinkSetQuery;
```

## C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE StackID;
 UBYTE NumLinkSets;
 UBYTE Data[220];
} XL_SS7SignalingLinkSetQueryAck;
```

## C++ Class

```
class XLC_SS7SignalingLinkSetQuery : public
 XLC_OutboundMessage {
public:
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
};
```

## C++ Class Response

```
class XLC_SS7SignalingLinkSetQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;

| <b>Description</b>    | This message allows the host to assign or to deconfigure a signaling route to reach a specific DPC. Each assigned route to a DPC is given an associated priority route selection in the presence of multiple available routes for a DPC. |
| <b>Sent by</b>        | Host                                                                                                                                                                                                                                     |

| <b>SwitchKit Name</b> | SS7SignalingRouteQuery                                                                                                                                                |
| <b>Type</b>           | EXS API and SwitchKit API message                                                                                                                                     |
| <b>Description</b>    | This message retrieves the configuration and status of all indicated signaling routes. This message can also be used to query the Destination ID, given the Route ID. |
| <b>Sent by</b>        | Host                                                                                                                                                                  |
| <b>SwitchKit Code</b> | <b>C Structure</b>                                                                                                                                                    |

```
typedef struct {
 UBYTE StackID;
 unsigned short Destination;
 unsigned short RouteID;
} XL_SS7SignalingRouteQuery;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE StackID;
 unsigned short Destination;
 unsigned short RouteID;
 int DPC;
 UBYTE LinkSetID;
 UBYTE Priority;
 UBYTE DestinationStatus;
 UBYTE RouteStatus;
} XL_SS7SignalingRouteQueryAck;
```

### C++ Class

```
class XLC_SS7SignalingRouteQuery : public
 XLC_OutboundMessage {
public:
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 unsigned short getDestination() const;
 void setDestination(unsigned short x);
 unsigned short getRouteID() const;
 void setRouteID(unsigned short x);
};
```

### C++ Class Response

```
class XLC_SS7SignalingRouteQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getStackID() const;
```

```

void setStackID(UBYTE x);
unsigned short getDestination() const;
void setDestination(unsigned short x);
unsigned short getRouteID() const;
void setRouteID(unsigned short x);
int getDPC() const;
void setDPC(int x);
UBYTE getLinkSetID() const;
void setLinkSetID(UBYTE x);
UBYTE getPriority() const;
void setPriority(UBYTE x);
UBYTE getDestinationStatus() const;
void setDestinationStatus(UBYTE x);
UBYTE getRouteStatus() const;
void setRouteStatus(UBYTE x);
};

# SS7 Signaling Stack Configure 0x005C

---

**SwitchKit Name** SS7SignalingStackConfig

**Type** EXS API and SwitchKit API message

**Description** Use this message to define a signaling stack, which includes assigning an OPC and a variant. You can also use this message to deconfigure a signaling stack.

**NOTE:** PCM encoding for CICs controlled by the signaling stack is defaulted based on the network signaling variant. ANSI stacks default to u-law regardless of the physical link type. ITU stacks default to A-law. To change the encoding format see the PCM Encoding Format message.

**Sent by:** Host

**SwitchKit Code** **Configuration**

```
SS7SignalingStackConfig (
 Node = integer,
 Slot = integer,
 Stack = integer,
 OPC = integer,
 NumModules = integer,
 Data = byte array);
```

## C Structure

```
typedef struct {
 UBYTE Slot;
 UBYTE Stack;
 int OPC;
 UBYTE NumModules;
 UBYTE Data[218];
} XL_SS7SignalingStackConfig;
```

## C++ Class

```
class XLC_SS7SignalingStackConfig : public
 XLC_OutboundMessage {
public:
 UBYTE getSlot() const;
 void setSlot(UBYTE x);
 UBYTE getStack() const;
 void setStack(UBYTE x);
 int getOPC() const;
 void setOPC(int x);
 UBYTE getNumModules() const;
 void setNumModules(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
```

**EXS API Hex Format**

| 11 | <p>Module 1: Type</p> <p>0x01 MTP (Message Transfer Part)<br/> <b>Required</b> for any SS7 configuration or for BT IUP</p> <p>0x02 ISUP (ISDN User Part)<br/> <b>Required</b> if you are using the ISUP Call Control User Part</p> <p>0x03 L3P (Layer 3 Plus)<br/> <b>Required</b> for any SS7 configuration</p> <p>0x04 TUP (Telephone User Part)<br/> <b>Required</b> if you are using the TUP Call Control User Part</p> <p>0x05 L3P TUP/BT IUP (Layer 3 Plus for Telephone User Part/BT IUP)<br/> <b>Required</b> if you are using the TUP or BT IUP Call Control User Part</p> <p>0x06 SCCP</p> <p>0x07 TCAP</p> <p>0x08 M3UA</p> <p>When using BT IUP, you must configure MTP. For example, if you are configuring the ISUP Call Control User Part, then you would send this message with three sets of module <i>Type</i> and <i>Variant</i> fields: MTP, L3P, and ISUP.</p> <p>When using the BT IUP variant, the Module Variant is 0x02. You must also configure module types 0x01 and 0x03. For example, in an E1 configuration, you would specify Module Type 0x01 with a variant of 0x01, Module 3 with a variant of 0x01, Module 4 with a variant of 0x02, and Module 5 with a variant of 0x02.</p> |
| :  | Module 1: Variant (see information below this table)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Module Variant** The following variants are tested and supported.

| Value | Description | Modules                                      |
|-------|-------------|----------------------------------------------|
| 0x00  | ANSI '97    | All Modules (except TUP or BT IUP)           |
| 0x01  | ITU-TS '97  | All Modules                                  |
| 0x02  | BT IUP      | Module Types 4 and 5 when BT IUP is required |
| 0x03  | SSUTR2      | Module Types 4 and 5 when BT IUP is required |
| 0x08  | JT          | Module Type 1 only                           |

## SS7 Signaling Stack Query 0x006D

---

|                       |                                                                    |
|-----------------------|--------------------------------------------------------------------|
| <b>SwitchKit Name</b> | SS7SignalingStackQuery                                             |
| <b>Type</b>           | EXS API and SwitchKit API message                                  |
| <b>Description</b>    | This message retrieves the configuration of an SS7signaling stack. |
| <b>Sent by</b>        | Host                                                               |

### SwitchKit Code C Structure

```
typedef struct {
 UBYTE StackID;
} XL_SS7SignalingStackQuery;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE StackID;
 int OPC;
 UBYTE NumModules;
 UBYTE Data[216];
} XL_SS7SignalingStackQueryAck;
```

### C++ Class

```
class XLC_SS7SignalingStackQuery : public
 XLC_OutboundMessage {
public:
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
};
```

### C++ Class Response

```
class XLC_SS7SignalingStackQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 int getOPC() const;
 void setOPC(int x);
 UBYTE getNumModules() const;
 void setNumModules(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**EXS API Hex Format**

| <b>Description</b>    | <p>This message allows the host to modify the format of a TUP message in the TUP Message Configuration template. The template of each message is used to format outgoing messages and to interpret incoming messages.</p> <p>You can use up to a maximum of eight mandatory fields and 12 optional fields per message. You can use a maximum of eight subfields per field.</p> <p>Use the <i>SS7 TUP Message Query</i> message to retrieve the currently configured format of a TUP message.</p> <p>Modifying the format of an TUP message may also require modification of its PPL Configuration Bytes.</p> |

```

### C Structure

```
typedef struct {
 UBYTE StackID;
 UBYTE TUPMessageIndex;
 UBYTE MCTEntry;
 UBYTE H0Length;
 UBYTE H0Value;
 UBYTE H1Length;
 UBYTE H1Value;
 unsigned short MsgAttributes;
 UBYTE Data[215];
} XL_SS7TUPMessageFormatConfig;
```

### C++ Class

```
class XLC_SS7TUPMessageFormatConfig : public
 XLC_OutboundMessage {
public:
 UBYTE getStackID() const;
```

```

void setStackID(UBYTE x);
UBYTE getTUPMessageIndex() const;
void setTUPMessageIndex(UBYTE x);
UBYTE getMCTEntry() const;
void setMCTEntry(UBYTE x);
UBYTE getH0Length() const;
void setH0Length(UBYTE x);
UBYTE getH0Value() const;
void setH0Value(UBYTE x);
UBYTE getH1Length() const;
void setH1Length(UBYTE x);
UBYTE getH1Value() const;
void setH1Value(UBYTE x);
unsigned short getMsgAttributes() const;
void setMsgAttributes(unsigned short x);
const UBYTE *getData() const;
UBYTE *getData();
void setData(UBYTE *x);
};

```

**EXS API Hex Format**

**NOTE:** The fields listed between the double lines in the table (*Field[m]* ñ *ID* through *Subfield[s]* ñ *Maximum Length, LSB*) are repeated for each mandatory field. Likewise, the fields listed between the thick lines in the table (*Field[o]* ñ *ID* through *Subfield[s]* ñ *Maximum Length, LSB*) are repeated for each optional field. Each mandatory and optional field can have a variable number of subfields. For example, Mandatory Field[0] can have 3 subfields, Mandatory Field[1] can have two subfields, and Optional Field[0] can have 4 subfields.

**H0/H1 Length**

The system uses the H0 and H1 fields as  $x, y$  coordinates for the Heading Code Allocations table found in the Q.723 specification.

This field indicates whether length of the *H0 Value* and *H1 Value* fields are defined as half-octets or octets (groups of 4 bits or 8 bits, respectively). Valid entries for this field are as follows:

- 0x01 Half-octets
- 0x02 Octets

**H0/H1 Value**

The system uses the H0 and H1 fields as  $x, y$  coordinates for the Heading Code Allocations table found in the Q.723 specification.

**TUP** This field represents the value of the H0 or H1 parameter in the Heading Code Allocations table. To represent the appropriate Heading Code, use the following H0 and H1 values:

| Heading | H0   | H1   |
|---------|------|------|
| IAM     | 0x01 | 0x01 |
| IAI     | 0x01 | 0x02 |

## SS7 TUP Message Query 0x0090

---

|                       |                                                                          |
|-----------------------|--------------------------------------------------------------------------|
| <b>SwitchKit Name</b> | SS7TUPMessageQuery                                                       |
| <b>Type</b>           | EXS API and SwitchKit API message                                        |
| <b>Description</b>    | This message reports the configured format of the specified TUP message. |
| <b>Sent by</b>        | Host                                                                     |

### SwitchKit Code C Structure

```
typedef struct {
 UBYTE StackID;
 UBYTE TUPMessageIndex;
} XL_SS7TUPMessageQuery;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE StackID;
 UBYTE TUPMessageIndex;
 UBYTE MCTEntry;
 UBYTE H0Length;
 UBYTE H0Value;
 UBYTE H1Length;
 UBYTE H1Value;
 unsigned short MsgAttributes;
 UBYTE Data[213];
} XL_SS7TUPMessageQueryAck;
```

### C++ Class

```
class XL_SS7TUPMessageQuery : public XLC_OutboundMessage
{
public:
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 UBYTE getTUPMessageIndex() const;
 void setTUPMessageIndex(UBYTE x);
};
```

### C++ Class Response

```
class XL_SS7TUPMessageQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getStackID() const;
 void setStackID(UBYTE x);
 UBYTE getTUPMessageIndex() const;
 void setTUPMessageIndex(UBYTE x);
 UBYTE getMCTEntry() const;
```

```

void setMCTEntry(UBYTE x);
UBYTE getH0Length() const;
void setH0Length(UBYTE x);
UBYTE getH0Value() const;
void setH0Value(UBYTE x);
UBYTE getH1Length() const;
void setH1Length(UBYTE x);
UBYTE getH1Value() const;
void setH1Value(UBYTE x);
unsigned short getMsgAttributes() const;
void setMsgAttributes(unsigned short x);
const UBYTE *getData() const;
UBYTE *getData();
void setData(UBYTE *x);
};

```

**EXS API Hex Format**

**NOTE:** The fields listed between (*Field[m] – ID* through *Subfield[s] – Maximum Length, LSB*) are repeated for each mandatory field. Likewise, the fields listed between (*Field[o] – ID* through *Subfield[s] – Maximum Length, LSB*) are repeated for each optional field.

Each mandatory and optional field can have a variable number of subfields. For example, Mandatory Field[0] can have 3 subfields, Mandatory Field[1] can have two subfields, and Optional Field[0] can have 4 subfields.

**H0/H1 Length**

The system uses the H0 and H1 fields as *x, y* coordinates for the Heading Code Allocations table found in the Q.723 specification.

This field indicates whether length of the *H0 Value* and *H1 Value* fields are defined as half-octets or octets (groups of 4 bits or 8 bits, respectively). Valid entries for this field are as follows:

0x01 Half-octets

0x02 Octets

**H0/H1 Value**

The system uses the H0 and H1 fields as *x, y* coordinates for the Heading Code Allocations table found in the Q.723 specification.

This field represents the value of the H0 or H1 parameter in the Heading Code Allocations table. To represent the appropriate Heading Code, use the following H0 and H1 values:

| Heading | H0   | H1   |
|---------|------|------|
| IAM     | 0x01 | 0x01 |

| <b>Type</b>                                              | EXS API and SwitchKit API message                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>                                       | This message allows the host in a redundant system to configure a line card as a standby card. Only line cards that have Standby IO cards behind them can be designated as standby line cards. A <i>Card Status Report</i> message first informs the host which line card has a Standby I/O installed. The host must assign a line card as a standby before a switchover can occur. |
| <b>Sent by</b>                                           | Host                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Example Message (Socket Log Output for SwitchKit)</b> | In the following socket log output/example message, the host configures a T-ONE card to be a standby card:                                                                                                                                                                                                                                                                          |

| <b>Description</b>    | <p><b>NOTE:</b> This message applies to the DSP Series 2 card only.</p> <p>Use this message to query cache and function usage statistics that are kept on the DSP Series 2 card. The statistics are stored in cache for 16 days, and then they are replaced one-by-one with more recent statistics. At any time, you can view statistics for the past 16 days. You can configure the time to copy statistics into the buffer from one second to 86,400 seconds, in one-second increments.</p> <p>This message does not support wildcards for the DSP Chip AIB, because the data that comes back from the CSP would be too long.</p> |
| <b>Sent by</b>        | Host Application                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## SwitchKit Code C Structure

```
typedef struct {
 unsigned short Status;
 UBYTE reserved6[13];
 UBYTE TLVCount;
 UBYTE Data[250];
} XL_StatisticsQuery;
```

## C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE reserved[13];
 UBYTE AddrInfo[251];
 UBYTE TLVCount;
 UBYTE Data[250];
} XL_StatisticsQueryAck;
```

## C++ Class

```
class XLC_StatisticsQuery : public XLC_OutboundMessage {
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);

 // Extended addressing functions
 // DSP Chip AIB functions
 void DSPChip(UBYTE x);
 UBYTE getDSPSlot() const;
 void setDSPSlot(UBYTE x);
 UBYTE getDSPSIMM() const;
```

```
void setDPSIMM(UBYTE x);
// Slot AIB functions
UBYTE getSlot() const;
void setSlot(UBYTE x);
UBYTE getDataType() const;
void setDataType(UBYTE x);
UBYTE getTLVCount() const;
void setTLVCount(UBYTE x);
const UBYTE *getData() const;
UBYTE *getData();
void setData(UBYTE *x)
};
```

### **C++ Class Response**

```
class XLC_StatisticsQueryAck : public XLC_OutboundMessage
{
public:

 unsigned short getStatus() const
 void setStatus(unsigned short x)
 UBYTE getTLVCount() const;
 void setTLVCount(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x)
 ;
};
```

**Address Element 0x25 - Subrate Channel**

Use the Subrate Channel Address Type to address two subrate channels.

For a 1-way connection, enter the source subrate channel in Address Element 1 and the destination subrate channel in Address Element 2.

For a 1-way disconnect, enter the subrate channel to be disconnected in both Address Element 1 and Address Element 2.

# SwitchBackFromStandby

---

**Type** SwitchKit API message

**Description** Use the *SK\_SwitchBackFromStandby* message to initiate a switchback from a standby line card to the primary one. This message can only be sent if the action field of the message *SK\_SwitchBackFromStandbyConfig* is set to 1 during configuration.

**Sent by** Application or Converged Services Administrator (CSA).

**Arguments** The following table shows the arguments that you can modify:

| Argument    | Description                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Action      | This field can be set to: <ul style="list-style-type: none"> <li>0 = graceful switchback after LLC determines that the standby card is not handling any calls.</li> <li>1 = forced switchback immediately.</li> </ul> |
| Node        | Specifies the node where the switchback is supposed to happen.                                                                                                                                                        |
| StandbySlot | Specifies the standby slot of the redundant card.                                                                                                                                                                     |

**C Structure**

```
typedef struct {
 UBYTE StandbySlot;
 UBYTE Action;
} SK_SwitchBackFromStandby;
```

**C Structure Response**

```
typedef struct {
 int Status;
} SK_SwitchBackFromStandbyAck;
```

**C++ Class**

```
class SKC_SwitchBackFromStandby : public
 SKC_ToolkitMessage {
public:
 UBYTE getStandbySlot() const;
 void setStandbySlot(UBYTE x);
 UBYTE getAction() const;
 void setAction(UBYTE x);
};
```

**C++ Class Response**

```
class SKC_SwitchBackFromStandbyAck : public
 SKC_ToolkitAck {
public:
 int getStatus() const;
 void setStatus(int x);
```

SwitchBackFromStandby

};

# SwitchMgrQuery

---

**Type** SwitchKit API message

**Description** Use the *SK\_SwitchMgrQuery* to allow an application to find out the current configuration state of the SwitchManager. If the SwitchManager is in the process of configuring when an application connects to LLC, *SK\_SwitchMgrQuery* will notify the application of this state.

If you have the application/LLC set to channel recovery method 2 or 3, where channels are taken out of service, it is the application's responsibility to take the channels back into service when the first application watching a specific channel group connects to LLC using *ForceGroupState*. Without *SK\_SwitchMgrQuery*, when SwitchManager is being started while the application is also starting up, there may be a condition where the application will take channels inservice prior to the configuration being complete. This can cause critical configuration messages from SwitchManager to fail since the channel is already in-service.

**Sent by** Application or Converged Services Administrator (CSA).

**Arguments** The following table shows the arguments that you can modify:

| Argument  | Description                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QueryType | This field can be set to: <ul style="list-style-type: none"> <li>0 = SK_SMQ_CONFIG_STATUS</li> <li>0 = SK_SMQ_IDLE</li> <li>1 = SK_SMQ_CONFIGURING</li> </ul> |

**C Structure**

```
typedef struct {
 UBYTE QueryType;
 UBYTE reserved18[252];
} SK_SwitchMgrQuery;
```

**C Structure Response**

```
typedef struct {
 unsigned short DataSize;
 int Status;
 UBYTE TLVCount;
 UBYTE Data[246];
} SK_SwitchMgrQueryAck;
```

**C++ Class** `class SKC_SwitchMgrQuery : public SKC_ToolkitMessage {`

```
public:
 UBYTE getQueryType() const;
 void setQueryType(UBYTE x);
};
```

**C++ Class Response**

```
class SKC_SwitchMgrQueryAck : public SKC_ToolkitAck {
public:
 unsigned short getDataSize() const;
 void setDataSize(unsigned short x);
 int getStatus() const;
 void setStatus(int x);
 UBYTE getTLVCount() const;
 void setTLVCount(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

# Synchronization Priority List Query 0x0081

---

|                       |                                                                                                         |
|-----------------------|---------------------------------------------------------------------------------------------------------|
| <b>SwitchKit Name</b> | SynchPriorityQuery                                                                                      |
| <b>Type</b>           | EXS API and SwitchKit API message                                                                       |
| <b>Description</b>    | This message is used to query the system's clock source priority list, and the source currently in use. |
| <b>Sent by</b>        | Host                                                                                                    |

## SwitchKit Code C Structure

```
typedef struct {
 } XL_SynchPriorityQuery;
```

## C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE CurrentMode;
 UBYTE Priority1Mode;
 UBYTE Priority2Mode;
 UBYTE Priority3Mode;
 UBYTE Priority4Mode;
 UBYTE Priority5Mode;
 } XL_SynchPriorityQueryAck;
```

## C++ Class

```
class XLC_SynchPriorityQuery : public XLC_OutboundMessage
{
public:
 };
```

## C++ Class Response

```
class XLC_SynchPriorityQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getCurrentMode() const;
 void setCurrentMode(UBYTE x);
 UBYTE getPriority1Mode() const;
 void setPriority1Mode(UBYTE x);
 UBYTE getPriority2Mode() const;
 void setPriority2Mode(UBYTE x);
 UBYTE getPriority3Mode() const;
 void setPriority3Mode(UBYTE x);
 UBYTE getPriority4Mode() const;
 void setPriority4Mode(UBYTE x);
 UBYTE getPriority5Mode() const;
 void setPriority5Mode(UBYTE x);
 };
```

|                                                          |                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SwitchKit Name</b>                                    | SystemConfig                                                                                                                                                                                                                                                          |
| <b>Type</b>                                              | EXS API and SwitchKit API message                                                                                                                                                                                                                                     |
| <b>Description</b>                                       | <p>This message configures system, non-related options. Those options include:</p> <ul style="list-style-type: none"> <li>• Message Resend Logic</li> <li>• Host Link Failure Detection Logic</li> <li>• System Busy Warning</li> <li>• Resource Threshold</li> </ul> |
| <b>Sent by</b>                                           | Host Application                                                                                                                                                                                                                                                      |
| <b>Example Message (Socket Log Output for SwitchKit)</b> | The following socket log output/example message shows the line card in slot 01 configured not to resend unacknowledged messages.                                                                                                                                      |

```
00 07 00 AF 00 00 FF 02 00
```

### SwitchKit Code Configuration

```
SystemConfig (
 Node = integer,
 ConfigType = integer,
 Data = byte array);
```

**NOTE:** Data must contain the Slot AIB first:

```
0x00 0x01 0x01 0x01 SlotNumber
then the Data of the message as usual.
```

### Example

This is an example of a SwitchManager message:

```
SystemConfig(Node=1, ConfigType=9,
 Data=0x00:0x01:0x01:0x01:0x05:
 0x01:0x04:0x00:0x01:0x02:0x03);
```

In this example, the slot number is: 0x00:0x01:0x01:0x01 in the slot AIB; and the data parameters of the message are: 0x01:0x04:0x00:0x01:0x02:0x03.

### C Structure

```
typedef struct {
 UBYTE ConfigType;
 UBYTE Data[252];
} XL_SystemConfig;
```

**C++ Class**

```

class XLC_SystemConfig : public XLC_OutboundMessage {
public:
 UBYTE getConfigType() const;
 void setConfigType(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};

```

**Overview of message**    The following table provides an overview of this message. The table following it provides the detail for each byte.

| MESSAGE (White) |                         | RESPONSE (Gray) |                       |
|-----------------|-------------------------|-----------------|-----------------------|
| Byte            | Field Description       | Byte            | Field Description     |

: **0x02 Message Resend Logic**

Data[0] Options

- 0x00 Do Not Resend  
Does not resend unacknowledged messages.
- 0x01 Resend Once (Default)\*
- 0x02 Resend Once and Generate *Alarm* Message
- 0x03 Resend Until Acknowledged\*  
Resends the message until acknowledged by the host.  
This applies to the following messages only: *Alarm*, *Alarm Cleared*,  
*Request For Service*, *Request For Service with Data*, and  
*Channel Released*.
- 0x04 Disable "Resend Until Acknowledged"  
Do not resend the messages listed above until acknowledged by the  
host. This cancels "Resend Until Acknowledged."

\*To enable "Resend Until Acknowledged" you must also enable "Resend Once"

**0x03 Host Link Failure Detection Logic**

Data[0] Feature Enable/Disable

- 0x00 Disable Host Link Failure Detection (Default)
- 0x01 Enable Host Link Failure Detection

Data[1] Response to Host Link Failure (HLF)

Bit 0 Setting for whether spans and channels will be taken out-of-service  
 0 Set all channels out of service when host link failure detected (Default)  
 1 Set all spans and channels out of service when host link failure  
 detected

Bit 1 Setting for whether a response will be sent when an HLF is detected  
 0 A response will be sent  
 1 No response will be sent

Bit 2 Setting for taking SCCP/TCAP out-of-service  
 0 Do not take SCCP/TCAP out-of-service  
 1 Take SCCP/TCAP out-of-service

Data[2,3] Failure Detection Timer  
 Value expressed in 10 ms units

## 0x06 System Busy Warning

Data[0] Sensitivity Level  
 0x00 Least Sensitive  
 0x01 :  
 0x02 :  
 0x03 :  
 0x04 :  
 0x05 Most Sensitive

Data[1] System Busy Warning  
 0x00 Disable (Default)  
 0x01 Enable

## 0x07 Resource Threshold

Data[0] Resource Type  
 0x01 Conferencing Timeslots

Data[1,2] Number of Assigned Timeslots to Generate an *Alarm Cleared* message  
 Data[3,4] Number of Assigned Timeslots to Generate an *Alarm* message

## 0x09 Resource Usage Reporting

Data[0] 0x00 Disable (Default)  
 0x01 Enable (Default interval is 5 minutes)  
 0x02 Change the Reporting Interval

Data[1] If Data[0] above is 0x00 (Disable) or 0x01 (Enable):  
 Number of Resources

If Data[0] above is 0x02 (Change the Reporting Interval):  
 Number of Minutes (Max: 254)

Data [2-N] Resource ID 1- Resource ID N:

NOTE: If Data[0] above is 0x02, Data[2-N] do not apply.

0x00 Memory  
 0x01 MCB  
 0x02 CPU Level 1  
 0x03 CPU Level 2

### 0x0B Approaching Busy Threshold for Slots

Data[0]

0x00 Disable

0x01 Enable

Default value for resource memory, MCB, and CPU usage is 80 per cent.

0x02 Change Thresholds

Data[1] Number of Resources

Data[2-N] Resource ID 1- Resource ID N:

0x00 Memory (percentage, expressed in Hex)

0x01 MCB (percentage, expressed in Hex)

0x02 CPU Usage (percentage, expressed in Hex)

### 0x0C Real Busy Threshold for Slots

Data[0]

0x00 Disable Alarm (Default)

0x01 Enable Alarm

Default value for resource memory, MCB, and CPU usage is 90 percent.

0x02 Change Thresholds

Data[1] Number of Resources

Data[2-N] Resource ID 1- Resource ID N:

0x00 Memory (percentage, expressed in Hex)

0x01 MCB (percentage, expressed in Hex)

0x02 CPU Usage (percentage, expressed in Hex)

## System Configuration Query 0x00B4

---

**SwitchKit Name** SystemConfigQuery

**Type** EXS API and SwitchKit API message

**Description** Use this message to query various configuration settings in the CSP. Some query results are reported in the response to the message, while others generate a *Generic Report* message.

**NOTE:** The acknowledgment for Active Conference IDs (query type 0x04) will return partial data — only the number of conferences. The report will have the remaining data, that is, all the conference IDs.

The data for the following Query Types is returned in the response:

- 0x02 - Message Resend Logic
- 0x03 - Host Link Failure Detection Logic
- 0x04 - Active Conference IDs
- 0x06 - System Busy Warning
- 0x17 - Extended Conference Enable

The data for the following Query Types is returned in the *Generic Report* message:

- 0x04 - Active Conference IDs
- 0x05 - Channel State
- 0x07 - Resource Threshold
- 0x09 - Resource Usage Reporting
- 0x0B - Approaching Busy Threshold for Slots
- 0x0C - Real Busy Threshold for Slots
- 0x10 - Detailed Conference Information
- 0x11 - DSP Resource Threshold
- 0x13 - Conference Speakers
- 0x14 - Conferencing Features
- 0x15 - Child Conference Information
- 0x16 - Child Conference IDs
- 0x18 - Cache File Query

### For SwitchKit

To get this report, you must register for it by calling the `sk_msgRegister` function with the parameter, `SK_RESOURCE_UTIL_REPORT`.

**Sent by** Host Application

**SwitchKit Code    C Structure**

```
typedef struct {
 UBYTE AddrInfo[30];
 UBYTE QueryType;
 UBYTE Data;
 UBYTE reserved49[221];
} XL_SystemConfigQuery;
```

**C Structure Response**

```
typedef struct {
 unsigned short Status;
 UBYTE reserved6[13];
 UBYTE Data[251];
} XL_SystemConfigQueryAck;
```

**C++ Class**

**NOTE:** The functions, `getDataBlock()` and `setDataBlock()`, should be used only for `QueryType 0x18`. The `setData()` function should not be used for this `QueryType`.

```
class XLC_SystemConfigQuery : public XLC_OutboundMessage
{
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 XBYTE getStartSpan() const;
 void setStartSpan(XBYTE x);
 UBYTE getStartChannel() const;
 void setStartChannel(UBYTE x);
 XBYTE getEndSpan() const;
 void setEndSpan(XBYTE x);
 UBYTE getEndChannel() const;
 void setEndChannel(UBYTE x);
 XBYTE getConferenceID() const;
 void setConferenceID(XBYTE x);
 XBYTE getParentConferenceID() const;
 void setParentConferenceID(XBYTE x);
 XBYTE getChildConferenceID() const;
 void setChildConferenceID(XBYTE x);
 UBYTE getSlot() const;
 void setSlot(UBYTE x);
 UBYTE getQueryType() const;
 void setQueryType(UBYTE x);
 UBYTE *getData() const;
 void setData(UBYTE *x);
 const UBYTE *getDataBlock() const;
 UBYTE *getDataBlock();
 void setDataBlock(UBYTE *x);
};
```

**C++ Class Response**    class **XLC\_SystemConfigQueryAck** : public  
                               **XLC\_AcknowledgeMessage** {

public:

```
unsigned short getStatus() const;
void setStatus(unsigned short x);
const UBYTE *getData() const;
UBYTE *getData();
void setData(UBYTE *x);
};
```

### EXS API Hex Format

| MESSAGE (White) |                       | RESPONSE (Gray) |                       |

**NOTE:** All counts are totals since last system power-up. All counts are reset when this message is received by the CSP.

## System Resource Usage Query 0x008E

---

**SwitchKit Name** SystemResourceUtilQuery

**Type** EXS API and SwitchKit API message

**Description** Use this message to query the utilization status of the following cards:  
T-ONE, E-ONE, SS7 Series 3, SS7 PQ, DSP, and Matrix Controller.

**Sent by** Host

**Sample Message** In the following sample, the host sends the System Resource Usage Query to the CSP to query the Resource Usage for a Card. Following is the response from the CSP.

### Host-to-CSP

00 10 00 8e 00 00 ff 02 00 01 01 01 09 04 00 01 02 03

### CSP-to-Host Response

00 5f 00 8e 00 00 ff 00 10 02 00 01 01 01 09 04 00 26 03 01  
02 00 02 48 c0 00 00 01 c0 03 00 02 63 00 00 00 00 00

a0 07 00 2d 19 02 00 32 04 00 4b 05 00 4b 06 01 00 07  
33 4b 32 03 00

**SwitchKit Code** **C Structure**

```
typedef struct {
 UBYTE QueryType;
 UBYTE Slot;
 UBYTE NumOfResources;
 UBYTE Data[221];
} XL_SystemResourceUtilQuery;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 UBYTE QueryType;
 UBYTE Data[250];
} XL_SystemResourceUtilQueryAck;
```

### **C++ Class**

```
class XLC_SystemResourceUtilQuery : public
 XLC_OutboundMessage {
public:
 UBYTE getQueryType() const;
 void setQueryType(UBYTE x);
 UBYTE getSlot() const;
 void setSlot(UBYTE x);
 UBYTE getNumOfResources() const;
 void setNumOfResources(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

### **C++ Class Response**

```
class XLC_SystemResourceUtilQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getQueryType() const;
 void setQueryType(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};

| <b>Description</b>                                       | This message is used to configure the characteristics of a T1 span.                                                                                                                 |
| <b>Sent by</b>                                           | Host                                                                                                                                                                                |
| <b>Example Message (Socket Log Output for SwitchKit)</b> | The following socket log output/example message shows a T1 Span being configured with D4 framing and a line coding method of bit 7 zero suppression. The line length is 0-133 feet. |

```
00 0D 00 A9 00 00 FF 00 01 0C 02 01 23 09 06
```

### SwitchKit Code Configuration

```
T1SpanConfig (
 Node = integer,
 Span = integer,
 Format1 = integer,
 Format2 = integer);
```

**NOTE:** In SwitchKit, the parameter Format1 is the same as Format in EXS API. In SwitchKit, the parameter Format2 is the same as Line Length in EXS API.

### C Structure

```
typedef struct {
 unsigned short Span;
 UBYTE Format1;
 UBYTE Format2;
} XL_T1SpanConfig;
```

### C++ Class

```
class XLC_T1SpanConfig : public XLC_SpanMessage {
public:
 unsigned short getSpan() const;
 void setSpan(unsigned short x);
 UBYTE getFormat1() const;
 void setFormat1(UBYTE x);
 UBYTE getFormat2() const;
 void setFormat2(UBYTE x);
};
```

**EXS API Hex Format**

## T1 Span Query 0x0085

---

|                       |                                                               |
|-----------------------|---------------------------------------------------------------|
| <b>SwitchKit Name</b> | T1SpanFormatQuery                                             |
| <b>Type</b>           | EXS API and SwitchKit API message                             |
| <b>Description</b>    | This message is used to query the configuration of a T1 span. |
| <b>Sent by</b>        | Host                                                          |

### SwitchKit Code C Structure

```
typedef struct {
 unsigned short Span;
} XL_T1SpanFormatQuery;
```

### C Structure Response

```
typedef struct {
 unsigned short Status;
 unsigned short Span;
 UBYTE Format;
 UBYTE LineLength;
} XL_T1SpanFormatQueryAck;
```

### C++ Class

```
class XLC_T1SpanFormatQuery : public XLC_OutboundMessage
{
public:
 unsigned short getSpan() const;
 void setSpan(unsigned short x);
};
```

### C++ Class Response

```
class XLC_T1SpanFormatQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 unsigned short getSpan() const;
 void setSpan(unsigned short x);
 UBYTE getFormat() const;
 void setFormat(UBYTE x);
 UBYTE getLineLength() const;
 void setLineLength(UBYTE x);
};
```

**EXS API Hex Format**

| <b>Description</b>    | <p>Each line card and Matrix Controller card has battery-backed RAM that stores configuration information provided by the host. This message allows the host to assign a tag to a card's configuration. after it has been configured. If the card configuration is modified, due to either CSP restoration of default values or host-initiated configuration commands, the tag is reset to 0.</p> <p>The tag is reported to the host in the <i>Card Status Report</i> and <i>Card Status Query</i> messages. With this feature, the host can quickly determine if a card has the proper configuration. When a card's configuration is modified, the tag is reset to 0, and the card must be retagged. In the event that the system is powered down, or a card is inserted, all battery-backed configuration is cleared.</p> |

| :               | Tag MSB, LSB<br>A two-byte number assigned by the host to identify a card's configuration.<br><br><b>NOTE:</b> The Tag value 0x0000 is reserved for untagged configurations.<br>The following is a list of the messages that would reset the configuration tag of a line card <b>only if they are successfully processed</b> (for example, the host receives a response Status of Positive Acknowledgment, 0x10). |                 |                       |

T-ONE, E-ONE, DS3

These messages reset the configuration tags of T-ONE, E-ONE, and DS3 cards:

- Answer Supervision Mode Configure
- Assign Logical Span ID
- B Channel Configure
- Busy Out Flag Configure
- D Channel Assign
- D Channel De-assign
- D Channel Facility List Configure
- DS3 Configure-Query (DS3 card only - when changing DS3 framer)
- Distant End Release Mode Configure
- E1 Span Configure
- Filter Timer Configure
- Flash Timing Configure
- Impulsing Parameter Configure
- Inseize Instruction List Configure
- Local End Release Mode Configure
- Outseize Instruction List Configure
- PCM Encoding Format Configure
- PPL Assign
- PPL Audit Configure
- PPL Configure
- PPL Timer Configure
- PPL Transmit Signal Configure
- Product License Download
- Receive Signaling Configure
- Service State Configure
- Span Filter Configure
- Start Dial Configure
- T1 Span Configure
- Transmit Signaling Configure
- Trunk Type Configure

J-ONE, SJ1LC

These messages reset the configuration tags of J-ONE cards:

- Assign Logical Span ID
- D Channel De-assign
- J1 Span Configure
- Service State Configure
- Span Filter Configure

DSP

These messages will reset the configuration tags DSP-ONE cards:

- Call Progress Analysis Class Configure
- Call Progress Analysis Pattern Configure
- DSP SIMM Configure
- Service State Configure
- Transmit Cadence Pattern Configure
- Transmit Tone Configure

|   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b>    | <p>This message is used to download system software files and to query the TFTP configuration. You can send this message no matter what state the Matrix Controller card is in.</p> <p>To download CSP software, send the Begin Download ICB as well as appropriate Data ICB subtypes to send the following information to the CSP:</p> <ul style="list-style-type: none"> <li>• Local Matrix Configuration Filename</li> <li>• Adjacent Matrix Configuration Filename</li> <li>• Local Matrix Server IP Address</li> <li>• Adjacent Matrix Server IP Address</li> <li>• Load Timestamp</li> </ul> <p>Send the Begin Download ICB whenever you assign a new TFTP configuration file that contains information about a new load.</p> <p>To query the TFTP configuration, send one of the Action ICB query subtypes. The response to a query includes the corresponding Data ICB subtype.</p> <p>The Timestamp ICB is required only if the timestamp is not in the configuration file.</p> <p>Save Options, Load Version &amp; Load Filename are CSP-initiated ICBs in response to the Query ICBs.</p> <p>Adjacent Matrix ICBs are needed only if you have an adjacent matrix, but they can also be sent directly to the adjacent matrix, instead of through the local matrix.</p> |

### Example Message (Socket Log Output for SwitchKit)

#### Query Local Matrix Filename

The trace below shows the *TFTP Manage* message sent from the host to the CSP to query the local matrix configuration filename. The bold number is the ICB Subtype, Query Local Matrix Configuration Filename (0x01).

#### Host to CSP:

```
[00 09] [00 3A] 00 00 FF 01 01 01 00
```

The trace below shows the response from the CSP. The bold numbers are the local matrix configuration filename, contained in a Query Local Matrix Configuration Filename action ICB (0x01).

#### CSP to Host:

```
[00 26] [00 3A] 00 00 FF [00 10] 01 01 01 [1B
 63 3A 5C 74 66 74 70 62 6F 6F 74 5C 74 66
 74 70 5F 6E 6F 5F 74 73 2E 63 66 67 00]
```

# Time Set 0x00B5

---

|                       |                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------|
| <b>SwitchKit Name</b> | TimeSet                                                                                       |
| <b>Type</b>           | EXS API and SwitchKit API message                                                             |
| <b>Description</b>    | This message allows the host to set the clock used by the CSP to timestamp fault log entries. |

## WARNING

*It is imperative that you set the system time properly.*

**Sent by** Host

### SwitchKit Code Configuration

```
TimeSet (
 Node = integer,
 Month = integer,
 Day = integer,
 Year = integer,
 Hour = integer,
 Minute = integer,
 Second = integer);
```

### C Structure

```
typedef struct {
 UBYTE Month;
 UBYTE Day;
 UBYTE Year;
 UBYTE Hour;
 UBYTE Minute;
 UBYTE Second;
} XL_TimeSet;
```

### C++ Class

```
class XLC_TimeSet : public XLC_OutboundMessage {
public:
 UBYTE getMonth() const;
 void setMonth(UBYTE x);
 UBYTE getDay() const;
 void setDay(UBYTE x);
 UBYTE getYear() const;
 void setYear(UBYTE x);
 UBYTE getHour() const;
 void setHour(UBYTE x);
 UBYTE getMinute() const;
 void setMinute(UBYTE x);
 UBYTE getSecond() const;
 void setSecond(UBYTE x);
```

};

**Example Message—Global Update of dBm Level**

The following is an example using the *Tone Configure* message to change the power levels of DTMF tones to: -4 dBm for low-band frequency, and -7 dBm for high-band frequency.

### Configuring a Sample Pattern ID

The following example shows how to configure Pattern ID 0x17 to receive a three-second, 400 Hz tone. To perform this task, the host sends three API messages. First, the host sends the *Tone Configure* message to replace the default tone (Tone ID 0x0F, 425 Hz) with the new, 400 Hz tone. Second, the host sends the *CPA Pattern Configure* message to create the new Pattern ID 0x17. Third, the host sends the *CPA Class Configure* message to add Pattern 0x17 to the CPA class 0x00.

#### First Message: *Tone Configure*

**Example: Query Call Progress Transmit Tone Frequency and Power**

This is an example of a message to query Call Progress Transmit Tone Frequency and Power per Tone ID for Tone ID Number 4 configured in the example for the *Tone Configure* message.

| Byte | Message Field          | Value  |
|------|------------------------|--------|
| 0    | Frame                  | 0xFE   |
| 1, 2 | Length                 | 0x0009 |
| 3, 4 | Message Type           | 0x005A |

# TransferChanMsg

---

**Type** SwitchKit API message

**Description** Use the *SK\_TransferChanMsg* message when an application requires a different application to receive messages associated with a channel.

Span and channel describe the channel that is to be transferred to the target application. This channel must already be assigned to the current application. The Tag and Data fields are passed along without modification. The target application receives *SK\_TransferChanMsg* with all the fields entered as they were entered by the sending application. The target application is then responsible for returning the channel to the LLC when it is finished with it.

**Important!** The span and channel must be specified in both the *TransferChanMsg* and the *TransferChanMsgAck* in order for the LLC to properly route this message to the appropriate applications. The channel is not physically transferred to the new application until the requesting application receives the Ack.

The application that receives the message must send a *SK\_TransferChanMsgAck* to let the sending application know that the message was received. This can be done with the following code:

```
int handleTransfer(SK_Event *evt, void *tag){
 MsgStruct *msg = evt->IncomingMsg;
 SK_MSG_SWITCH(msg) {
 CASE_TransferChanMsg(tcm) {
 SK_TransferChanMsgAck a;
 sk_initMsg(&a, TAG_TransferChanMsgAck);
 a.Status = 0x10;
 sk_setSeqNum(&a, sk_getSeqNum(tcm));
 sk_sendMsgStruct((MsgStruct *)&a, NULL, NULL);
 };
 };
};
```

**Sent by** Application

**C Structure**

```
typedef struct {
 unsigned short Span;
 UBYTE Channel;
 int Target;
 unsigned short AckTimeout;
 int Tag1;
 int Tag2;
```

```

int Tag3;
int Tag4;
char AppGroupTarget[16];
unsigned short DataSize;
UBYTE Data[210];
} SK_TransferChanMsg;

```

**C Structure Response**

```

typedef struct {
 int Status;
 unsigned short Span;
 UBYTE Channel;
 unsigned short AckTimeout;
 int Tag1;
 int Tag2;
 int Tag3;
 int Tag4;
 unsigned short DataSize;
 UBYTE Data[226];
} SK_TransferChanMsgAck;

```

**C++ Class**

```

class SKC_TransferChanMsg : public SKC_ToolkitMessage {
public:
 unsigned short getSpan() const;
 void setSpan(unsigned short x);
 UBYTE getChannel() const;
 void setChannel(UBYTE x);
 int getTarget() const;
 void setTarget(int x);
 unsigned short getAckTimeout() const;
 void setAckTimeout(unsigned short x);
 int getTag1() const;
 void setTag1(int x);
 int getTag2() const;
 void setTag2(int x);
 int getTag3() const;
 void setTag3(int x);
 int getTag4() const;
 void setTag4(int x);
 const char *getAppGroupTarget() const;
 void setAppGroupTarget(const char *x);
 unsigned short getDataSize() const;
 void setDataSize(unsigned short x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};

```

**C++ Class Response**

```

class SKC_TransferChanMsgAck : public SKC_ToolkitAck {
public:
 int getStatus() const;
 void setStatus(int x);
 unsigned short getSpan() const;
 void setSpan(unsigned short x);
 UBYTE getChannel() const;
 void setChannel(UBYTE x);
 unsigned short getAckTimeout() const;
 void setAckTimeout(unsigned short x);
};

```

```
int getTag1() const;
void setTag1(int x);
int getTag2() const;
void setTag2(int x);
int getTag3() const;
void setTag3(int x);
int getTag4() const;
void setTag4(int x);
unsigned short getDataSize() const;
void setDataSize(unsigned short x);
const UBYTE *getData() const;
UBYTE *getData();
void setData(UBYTE *x);
};
```

**SK\_BAD\_APP\_NAME** Target application does not exist.

**SK\_BAD\_PARAMETER** Invalid parameter. This includes when the channel specified by span and channel is not allocated to the source application.

**SK\_BAD\_MESSAGE** LLC is unable to send the TransferCan Msg to the target application.

| <b>Description</b>    | <p>This message is used to allow the host to configure any transmit cadence pattern. The host can create the cadence and the duration of the tone needed. Each cycle block shown below represents two durations, either of which could be silence (Tone ID=0) or some valid Tone ID. These cycle blocks can be repeated or strung together with different cycle blocks. For tones which are to be continuously on the duration should be set to 0xFFFF.</p> |
| <b>Sent by</b>        | Host                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## SwitchKit Code Configuration

```
TransmitCadencePatternConfig (
 Node = integer,
 UpdateFlag = integer,
 Action = integer,
 Data = byte array);
```

### C Structure

```
typedef struct {
 UBYTE UpdateFlag;
 UBYTE Action;
 UBYTE Data[251];
} XL_TransmitCadencePatternConfig;
```

### C++ Class

```
class XLC_TransmitCadencePatternConfig : public
 XLC_OutboundMessage {
public:
 UBYTE getUpdateFlag() const;
 void setUpdateFlag(UBYTE x);
 UBYTE getAction() const;
 void setAction(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**Overview of message**    The following table provides an overview of this message. The table following it, provides the detail for each byte.

**Example**

**NOTE:** To transmit the pattern continuously, do not set the “Number of times. . .” parameter in this message to 0xFFFF. Instead, set the appropriate parameter in the *Connect Tone Pattern* message. Please refer to the *Connect Tone Pattern* message for more information.

The following example shows the message contents that would be sent to configure a specific cadence pattern to be transmitted on any channel.

Durations are expressed in 10 ms units.

Configure Pattern: Pattern ID Number 2 (Ringback)

Cycle Block 1: Tone ID 4, 400 ms On/200 ms Off, execute once

Cycle Block 2: Tone ID 4, 400 ms On/3000 ms Off, execute once

| Byte | Message           | Value |

## SwitchKit Code Configuration

```
TransmitSignalingConfig (
 Node = integer,
 Range = StartSpan:StartChan - EndSpan:EndChan,
 SignallingType = integer,
 SignallingValue = integer,
 TransmissionMode = integer);
```

## C Structure

```
typedef struct {
 unsigned short StartSpan;
 UBYTE StartChannel;
 unsigned short EndSpan;
 UBYTE EndChannel;
 UBYTE SignallingType;
 UBYTE SignallingValue;
 UBYTE TransmissionMode;
} XL_TransmitSignalingConfig;
```

## C++ Class

```
class XLC_TransmitSignalingConfig : public
 XLC_ChangeRangeMessage {
public:
 unsigned short getStartSpan() const;
 void setStartSpan(unsigned short x);
 UBYTE getStartChannel() const;
 void setStartChannel(UBYTE x);
 unsigned short getEndSpan() const;
 void setEndSpan(unsigned short x);
 UBYTE getEndChannel() const;
 void setEndChannel(UBYTE x);
 UBYTE getSignallingType() const;
 void setSignallingType(UBYTE x);
 UBYTE getSignallingValue() const;
 void setSignallingValue(UBYTE x);
 UBYTE getTransmissionMode() const;
 void setTransmissionMode(UBYTE x);
};
```

**Example—Invert E&M Wink Start Signaling**

This example shows the message sequence sent to invert the default E&M Wink Start transmit signaling on a channel. The default E&M signaling values are: on-hook: A = 0, B = 0; all other signaling: A = 1, B = 1.

A separate message must be sent to change each signaling type.

| <b>Description</b>    | <p>The message is required only for the T-ONE card. It sets the trunk or line interface protocol for a channel or group of channels. Logical Span IDs must be assigned to channels before this message can be sent.</p> <p>This should be the first message sent when configuring channels, as any configuration sent before it resets to the defaults for the trunk type specified.</p> <p>Trunk types define the standard signaling protocol used by a channel or group of channels. The <i>Trunk Type Configure</i> message sets all of the channel configuration to the defaults associated with the trunk type (based on the AT&amp;T publication 43801 and the Bellcore TR-TSY-000506 specifications).</p> <p>The default trunk type is E&amp;M for T1 spans, and PPL (ITU-T Compelled R2) for E1 spans. Trunk types may be different for each individual channel on a span. This allows applications that require mixed trunk types to reside on the same span.</p> <p>Configuration associated with each trunk type include the start dial type, signal scanning filters and timers, and transmit signal timers. Any configuration which varies from the defaults must be reissued following the sending of a <i>Trunk Type Configure</i> message.</p> |

**NOTE:** This message cannot be used for channels on a T-ONE or E-ONE line card with the span format set to Clear Channel. If so, a NACK of 0x17 (Invalid Data Type) is returned.

# UpgradeSoftwarePatch

---

**TypeType** SwitchKit API message

**Description** Use the *SK\_UpgradeSoftwarePatch* message to upgrade node software specified by the functions **setNode**(UBYTE n) and **getNode**() of the base class SKC\_Message.

**Sent by** SwitchManager

**Arguments** The following table shows the arguments that you can modify:

| Argument | Description                                   |
|----------|-----------------------------------------------|
| Filename | File name of software patch to be downloaded. |

**C Structure**

```
typedef struct {
 char Filename[230];
} SK_UpgradeSoftwarePatch;
```

**C Structure Response**

```
typedef struct {
 int Status;
} SK_UpgradeSoftwarePatchAck;
```

**C++ Class**

```
class SKC_UpgradeSoftwarePatch : public
 SKC_ToolkitMessage {
public:
 const char *getFilename() const;
 void setFilename(const char *x);
};
```

**C++ Class Response**

```
class SKC_UpgradeSoftwarePatchAck : public SKC_ToolkitAck
{
public:
 int getStatus() const;
 void setStatus(int x);
};
```

# UserTimer

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Type</b>                       | SwitchKit API message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Purpose</b>                    | Use the <i><b>SK_UserTimer</b></i> message to cause an event to arrive at a predetermined time. The message that arrives at timer expiration is a <i><b>SK_UserTimerAck</b></i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>                | <p>The timer is tracked in the lower layers of the API, not by the LLC. It uses the socket-select mechanism for determining when the timer has expired which allows the timers to be operating system-independent, efficient, and relatively accurate. Without a real-time operating system, there is no guarantee of timing.</p> <p>There are no data fields in a <i><b>SK_UserTimer</b></i> message because, when sent with a tag through an appropriate toolkit sending function, a tag will also be associated with the acknowledgment that arrives after the time period has elapsed.</p>                                                                                                 |
| <b>Sent by</b>                    | Application                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>How to Set Up a Timer in C</b> | <p>In C, a variable of <i><b>SK_UserTimer</b></i> must be declared. The message must be initialized using <i><b>sk_initMsg()</b></i>. Then, the arguments must be initialized. Any of the SwitchKit send routines may be used to send the message and assign a message handler to handle the acknowledgement when the timer expires.</p> <pre> { ...     SK_UserTimer userTimer;     sk_initMsg(&amp;userTimer, TAG_UserTimer);     userTimer.Seconds = 5;     // Number of seconds until timer expires.     userTimer.GroupTag = 3;     // Used to identify timer upon cancellation     sk_sendMsgStruct((MsgStruct *)&amp;userTimer, (void     *)myData, timerExpiredHandler); ... }; </pre> |

### How to Set Up a Timer in C++

In C++, a object of class ***SKC\_UserTimer*** is created. Then, the arguments must be initialized using the `setSeconds()` and `setGroupTag()` methods of the class. The `send` method, which is a member of a base class inherited by ***SKC\_UserTimer***, can be used to send the message.

```
{
...
 SKC_UserTimer userTimer;
 userTimer.setSeconds(5);
 // Number of seconds until timer expires
 userTimer.setGroupTag(3);
 // Used to identify timer upon cancellation
 userTimer.send((void *)myData, timerExpiredHandler);
...
};
```

### Arguments

The following table shows the arguments you can change for *UserTimer*:

| Argument | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Seconds  | The delta time in seconds from when the <i>UserTimer</i> message is sent to when the <i>UserTimerAck</i> will be sent to indicate expiration of the timer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| GroupTag | Cancellation of a timer requires that GroupTag be set at creation of the timer. When you want to cancel a <i>UserTimer</i> , you need to send a <i>CancelUserTimer</i> message with the appropriate GroupTag. All currently unexpired UserTimer messages from that application with the corresponding GroupTag are canceled. It is important to realize that the GroupTag domain is unique to each application. This prevents one application from canceling another application's <i>UserTimer</i> . If multiple applications use the same GroupTag in a timer, and one application cancels that tag, only the timers from that application will be canceled. All other timers will still expire normally. |

### Return Status

The following table shows the possible return states:

| Value       | Description                      |
|-------------|----------------------------------|
| SK_SUCCESS  | Success                          |
| SK_CANCELED | Timer is cancelled (verify this) |

**C Structure**      typedef struct {  
                     float Seconds;  
                     int GroupTag;  
                     } ***SK\_UserTimer***;

**C Structure Response**      typedef struct {  
                             int Status;  
                             } ***SK\_UserTimerAck***;

**C++ Class**      class ***SKC\_UserTimer*** : public SKC\_ToolkitMessage {  
public:  
    float getSeconds() const;  
    void setSeconds(float x);  
    int getGroupTag() const;  
    void setGroupTag(int x);  
};

**C++ Class Response**      class ***SKC\_UserTimerAck*** : public SKC\_ToolkitAck {  
public:  
    int getStatus() const;  
    void setStatus(int x);  
};

| :   | <p>Query Type</p> <p>0x01 Query all host-configured V5 IDs (uses Slot AIB). Lists TLVs that are configured per slot represented by the "V5 Create" TLV</p> <p>0x02 Query all host-configured C Channels per V5 ID. Lists TLVs represented by the "V5 C Channel Assignment" TLV</p> <p>0x03 Query all host-configured links per V5 ID. Lists TLVs represented by the "V5 Add Link" TLV</p> <p>0x04 Query all other host-configured options per V5 ID. TLVs from the V5 Configure message are used in the response. The TLVs returned for this entity are as follows:</p> <ul style="list-style-type: none"> <li>• Variant ID (0x03)</li> <li>• Reserved type (0x08)</li> <li>• LE or AN side (0x05)</li> <li>• V5 Interface ID (0x10)</li> </ul> <p>0x05 Query all host-configured user ports per V5 ID. Lists TLVs represented by the "Add V5.2 User Port Range" TLV. Shows all the configured user ports as ranges for a queried V5 ID. A maximum of 50 ranges can be returned in a single response.</p> <p>0x06 Query the Service State of the V5 ID. A tag of "FF" is reported in the response. The service state of the V5 ID is reported in the response to this query.</p> <p>0x07 Host-configured User Port Range. A TLV represented by the "Add V5.2 User Port Range" TLV will show one range of the lowest configured user port ID to the highest configured user port for the queried V5 ID.</p> <p>0x08 Query all configured Cpaths. Lists TLVs represented by the "V5 C Path Assignment" TLV.</p> | :   | <p>TLVs</p> <p>0x0001 Create V5 ID</p> <p>0x0003 V5 Variant ID</p> <p>0x0004 V5 Variant Type</p> <p>0x0005 V5 Side</p> <p>0x0006 Add V5 User Port Range</p> <p>0x0008 Reserved</p> <p>0x0009 Reserved</p> <p>0x000A V5 C Channel Assignment</p> <p>0x000B V5 Cpath Assignment</p> <p>0x000C V5 Add Link</p> <p>0x000E Reserved</p> <p>0x0010 V5 Interface ID</p> |
| :   | Reserved (0x00)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | :   |                                                                                                                                                                                                                                                                                                                                                                  |

### SwitchKit Code Configuration

```
V5Config (
 ConfigType = integer,
 TLVCount = integer);
```

### C Structure

```
typedef struct {
 UBYTE AddrInfo[30];
 UBYTE ConfigType;
 UBYTE TLVCount;
 UBYTE Data[221];
} XL_V5Config;
```

### C++ Class

```
class XL_V5Config : public XLC_OutboundMessage {
public:
 const UBYTE *getAddrInfo() const;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 UBYTE getSlot() const;
 void setSlot(UBYTE x);
 XBYTE getV5ID() const;
 void setV5ID(XBYTE x);
 UBYTE getConfigType() const;
 void setConfigType(UBYTE x);
 UBYTE getTLVCount() const;
 void setTLVCount(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**EXS API Hex Format**

## **Response Status Indications**

The following response status indications are available for the V5 Configure message:

### **0x01 Invalid V5 Interface ID**

Internal slot initialization error for the V5 ID, or the host may be trying to:

- assign a V5 interface ID when this ID is already assigned in the CSP for the given network side (AN or LE).
- create a V5 ID that is greater than the maximum allowed.
- destroy a V5 ID that is greater than the maximum allowed.
- add a C Channel to a V5 ID that is not configured in the system.
- add a C Channel to a V5 ID that is greater than the maximum allowed.
- create a V5 ID that already exists.

### **0x02 Invalid TLV Length**

One or more TLVs used in this message have an incorrect length.

### **0x03 Unrecognized TLV Tag**

Unrecognized internal IMSG TLV tag was retrieved from IMSG.

### **0x04 Invalid V5 Variant ID**

A null pointer was encountered while attempting to configure the V5 variant ID for a V5 ID.

### **0x05 Invalid V5 Variant Type**

A null pointer was encountered while attempting to configure the V5 variant type.

### **0x06 Invalid Configuration Value**

- The host may be attempting to configure the network side as AN or LE and has passed an invalid value for the network side.
- A null pointer was configured while attempting to configure the network side.
- The host may have sent an invalid value for the Configure Type.

### **0x07 Invalid User Port ID Range**

- The host may be attempting to add a user port range when there were not enough free user port entries in the configuration database to accommodate the range.
- The host may be attempting to add a user port range when a user port ID within the desired range was already configured.
- The host may be attempting to add or remove a user port range that was invalid. The low range must be less than or equal to the high range and the total range must be less than or equal to the maximum allowed for each card.

See next RSV (0x08) for more information.

#### **0x08 Invalid Tag ID**

- The host may be attempting to add or remove a user port ID that is greater than the maximum allowed.
- The host may be attempting to add or remove a user port range that contained an incorrect user port type field.
- The host may be attempting to add or remove more ranges than are allowed (50).
- The host may have encountered a null pointer when attempting to add or remove user ports.

#### **0x09 V5 Interface is In Service**

The host may be attempting to add or remove a C Channel for an interface that was in service.

#### **0x0A Invalid C Channel**

- The host may be attempting to add or remove a C Channel that was greater than the maximum allowed per interface.
- The host may be attempting to add a C Channel to a timeslot that was already being used.
- The host may be attempting to add a C Channel with an invalid C Channel type value.
- The host may be attempting to add a C Channel to an interface that already has this logical C Channel assigned to it.
- The host was attempting to remove a C channel with an invalid C Channel ID.

#### **0x0B Invalid Link ID**

The host may be trying to:

- add a link with a span ID that is already assigned to another V5 interface.
- add a link when the link ID is already assigned to this V5 ID.
- add or remove a link ID that is greater than the maximum allowed.
- add a C Channel with a link ID that is not configured.
- remove a link that has a C Channel on it.
- add a link containing a C Channel to an interface that is in service.
- add a C Channel with a span ID that does not belong to the corresponding link ID.
- add a C Channel with a link ID that is greater than the maximum allowed.
- remove a link that is not configured.

**0x0C Duplicate User Port Assignment Attempt**

- The host may be attempting to add a duplicate user port ID to a V5 ID for a different Timeslot for V5.1.
- A null pointer was encountered

## Version Request 0x0002

|                 |                       | 23              | Checksum                                       |

### Notes:

1. If System Software Major Rev, System Software Minor Rev, and System Software build Number fields are “0,” system software is not present.
2. When in the process of downloading, the system software versions reflect the version of the code being downloaded. The version of the code which is being executed by the CSP may differ during download.
3. It is recommended that the host rely on the *Poll* message to determine when system software must be downloaded.
4. If a second Matrix Controller card is not installed, or if the system software is not present on the second Matrix Controller card, the *Adjacent Matrix Controller Timestamp* field will show “0.”
5. Timestamp equals number of seconds since January 1, 1970.

## Virtual Card Configure 0x00E0

| <b>Description</b>      | Use this message when configuring virtual spans to simulate the adding and removing of cards that do not exist in the system. The slot numbers you configure with this message are used when configuring the virtual spans. You must send this message prior to the <i>Assign Logical Span ID</i> message. |
|                         | <p><b>NOTE:</b> De-assigning all spans using the <i>Assign Logical Span ID</i> (0x00A8) message will clean up all virtual slots which acts as if the virtual cards were removed.</p>                                                                                                                       |

| <b>Type</b>            | EXS API and SwitchKit API message                                                                                           |
| <b>Description</b>     | This message is used by the host to indicate to the CSP the Layer 1 state of a Virtual Span.                                |
| <b>Sent</b>            | Host                                                                                                                        |
| <b>Example Message</b> | The following example brings all virtual spans in the node into service.<br>00 0E 00 E2 00 00 FF 00 01 0C 02 00 00 00 01 00 |

### SwitchKit Code Configuration

```
VirtualSpanControl (
 Node = integer,
 Span = integer,
 Event = integer,
 Data = byte array);
```

### C Structure

```
typedef struct {
 unsigned short Span;
 UBYTE reserved19[28];
 unsigned short Event;
 UBYTE Data[221];
} XL_VirtualSpanControl;
```

### C++ Class

```
class XLC_VirtualSpanControl : public XLC_SpanMessage {
public:
 unsigned short getSpan() const;
 void setSpan(unsigned short x);
 unsigned short getEvent() const;
 void setEvent(unsigned short x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**EXS API Hex Format**

## VoIP Protocol Configure 0x00EE

---

**SwitchKit Name** VOIPProtocolConfig

**Type** EXS API and SwitchKit API message

**Description** This message is used to configure H.323 and Session Initiation Protocol (SIP) software.

**Sent by** Host

**Example Message (Socket Log Output for SwitchKit)** The following socket log output/example message shows local SIP registrations enabled:

00 0E 00 EE 00 00 FF 00 00 00 00 01 01 C8 01 04

**Overview of message** The following table provides an overview of this message. The table following it, provides the detail for each byte.

| MESSAGE (White) |                          | RESPONSE (Gray) |                       |
|-----------------|--------------------------|-----------------|-----------------------|
| Byte            | Field Description        | Byte            | Field Description     |
| 0               | Frame (0xFE)             | 0               | Frame (0xFE)          |
| 1, 2            | Length (0xNNNN)          | 1, 2            | Length (0xNNNN)       |
| 3, 4            | Message Type (0x00EE)    | 3, 4            | Message Type (0x00EE) |
| 5               | Reserved (0x00)          | 5               | Reserved (0x00)       |
| 6               | Sequence Number          | 6               | Sequence Number       |
| 7               | Logical Node ID          | 7               | Logical Node ID       |
| 8               | <u>AIB</u>               | 8, 9            | Status MSB, LSB       |
| :               | Address Method           |                 |                       |
|                 | 0x00 Individual AEs      |                 |                       |
|                 | Number of AEs to follow  | 10              | Checksum              |
|                 | AEs                      |                 |                       |
| :               | Number of TLVs to follow |                 |                       |
| :               | TLVs                     |                 |                       |
| :               | :                        |                 |                       |
| :               | Checksum                 |                 |                       |

**SwitchKit Code Configuration**

```
VOIPProtocolConfig (
 Node = integer,
 Slot = integer
 TLVCount = integer,
 Data = string);
```

**NOTE:** The Slot parameter is needed only when configuring the H.323 protocol. SIP is configured automatically by SwitchKit.

**C Structure**

```
typedef struct {
 UBYTE AddrInfo[30];
 UBYTE TLVCount;
 UBYTE Data[222];
} XL_VOIPProtocolConfig;
```

**C++ Class**

```
class XLC_VOIPProtocolConfig : public XLC_OutboundMessage
{
public:
 const UBYTE *getAddrInfo() const ;
 UBYTE *getAddrInfo();
 void setAddrInfo(UBYTE *x);
 UBYTE getSlot() const };
 void setSlot(UBYTE x);
 UBYTE getTLVCount() const;
 void setTLVCount(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

### EXS API Hex Format - Detailed

## VoIP Protocol Query 0x00EF

---

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <b>SwitchKit Name</b> | VOIPProtocolQuery                                 |
| <b>Type</b>           | EXS API and SwitchKit API message                 |
| <b>Description</b>    | Use this message to query the VoIP configuration. |
| <b>Sent by</b>        | Host                                              |

**SwitchKit Code    C Structure**

```
typedef struct {
 UBYTE TLVCount;
 UBYTE Data[222];
} XL_VOIPProtocolQuery;
```

**C Structure Response**

```
typedef struct {
 unsigned short Status;
 UBYTE TLVCount;
 UBYTE Data[250];
} XL_VOIPProtocolQueryAck;
```

**C++ Class**

```
class XLC_VOIPProtocolQuery : public XLC_OutboundMessage
{
public:
 UBYTE getTLVCount() const
 void setTLVCount(UBYTE x)
 const UBYTE *getData() const
 UBYTE *getData()
 void setData(UBYTE *x);
};
```

**C++ Class Response**

```
class XLC_VOIPProtocolQueryAck : public
 XLC_AcknowledgeMessage {
public:
 unsigned short getStatus() const;
 void setStatus(unsigned short x);
 UBYTE getTLVCount() const;
 void setTLVCount(UBYTE x);
 const UBYTE *getData() const;
 UBYTE *getData();
 void setData(UBYTE *x);
};
```

**Overview of message** The following table provides an overview of this message. The table following it, provides the detail for each byte.

| MESSAGE (White) |                          | RESPONSE (Gray) |                       |
|-----------------|--------------------------|-----------------|-----------------------|

# WriteCfgFile

---

**Type**      SwitchKit API message

**Purpose**      Use the ***SK\_WriteCfgFile*** message to instruct SwitchManager to write the configuration file.

**Description**      When this message is received by SwitchManager, it will search through its database of messages for each slot on each node. Each message will be written to the new file.

**Sent by**      Application

**Arguments**      The following table shows the user modifiable arguments:

| Argument | Description                                                                                                                                                                                                                                                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filename | The name of the file to write to. If blank (e.g. ""), then SwitchManager will write to a filename derived from the input file. For example, if the original file is myConfig.cfg and no filename is provided to <i><b>SK_WriteCfg</b></i> , the first time <i><b>SK_WriteCfg</b></i> is called, the output name will be myConfig_1.cfg. |

**C Structure**

```
typedef struct {
 char Filename[230];
} SK_WriteCfgFile;
```

**C Structure Response**

```
typedef struct {
 int Status;
} SK_WriteCfgFileAck;
```

**C++ Class**

```
class SKC_WriteCfgFile : public SKC_ToolkitMessage {
public:
 const char *getFilename() const;
 void setFilename(const char *x);
};
```

**C++ Class Response**

```
class SKC_WriteCfgFileAck : public SKC_ToolkitAck {
public:
 int getStatus() const;
 void setStatus(int x);
 const UBYTE *getReserved() const;
 UBYTE *getReserved();
 void setReserved(UBYTE *x);
};
```

# 2 Address Elements

## Overview

---

**Purpose** This chapter lists the Address Elements (AEs) used in the EXS API. The single-byte (0xNN) AEs are first, listed in hexadecimal numerical order. They are followed by the double-byte (0xNNNN) AEs, also listed in hexadecimal numerical order.

# Introduction to Address Elements and Address Information Blocks

---

**Generic AIB Format** An Address Information Block (AIB) is used to address system objects, such as spans and channels. An AIB has a header, followed by one or more Address Elements. An Address Element is a group of data bytes that represent specific address information.

| AIB Field Description      |
|----------------------------|
| Address Method             |
| Number of Address Elements |
| Address Element Type       |
| Data Length (n)            |
| Data[0]                    |
| :                          |
| Data[n-1]                  |

## Address Method

Use this field to specify one of two methods for the AIB:

Individual or Range

0x00 - Individual AEs

The Individual AEs method treats each Address Element as a single entity. Use the Individual AEs method to address the following:

- A single component, such as a channel or a slot
- Multiple independent components that are not in a range, such as two channels in a *Connect* message, where Address Element 1 defines Channel A and Address Element 2 defines Channel B.

0x01 - Range

Use this method to define the two Address Elements that are the starting and ending entities in a range.

For example, you use this method in an *Impulsing Parameters Configure* message to configure a range of channels, where Address Element 1 defines the starting channel and Address Element 2 defines the ending channel.

**Important!** The field is contained in the AIB in the API messages not in the AE tables in this chapter.

### Number of Address Elements

This field indicates the number of Address Elements in the AIB.

An Address Element is a group of data bytes that describe an address. The number of data bytes in an Address Element varies, depending on the address element type.

**Important!** The field is contained in the AIB in the API messages not in the AE tables in this chapter.

### Address Element (AE) Type

This field specifies the Address Element (AE) type. An AIB can contain several AEs. PPL Components use Address Elements in various PPL Messages.

If you use the *Individual AEs* Addressing Method, you can insert multiple AEs, of different types, into a single AIB.

If you use the *Range* Addressing Method, you can insert two, and only two, Address Elements, and they must both be of the same Address Type.

### Data Length

This field indicates the number of data bytes in the AE immediately following this byte. If an AE contains no data, the value of this field is 0x00.

### Data[0]. . . Data[n]

The number of Address Elements in an AIB depends on the message, address type, and addressing requirements.

For example, the table below shows an AIB that has one Address Element, which in turn contains two data fields.

| Byte | AE Field Description        |
|------|-----------------------------|
| 2    | Address Element Type (0x12) |
| 3    | Data Length (0x02)          |
| 4    | Data[0] – Slot Number       |
| 5    | Data[1] – SIMM Number       |

### Using AIBs

To use AIBs in a message, perform the following steps:

1. Determine the required address method and address type. Each message shows the AIBs that are supported by that message. The AIBs are presented in tables similar to the one above. Remember to build flexibility into your applications to allow for future expansion of the API, including new AIB Address Methods and Types, new addressing requirements, and new functionality.
2. Insert the information, as defined in the table, into the AIB section of the message. The addressing requirements of the message determine the values for the *Address Method* and *Number of Address Elements* fields. The object being addressed determines the address data fields.

The table below shows how an AIB is inserted into an API message. The address data fields are bytes 12–13.

| MESSAGE |                        |                            |
|---------|------------------------|----------------------------|
| Byte    | Field Description      |                            |
| 0       | Frame Character (0xFE) |                            |
| 1       | Length, MSB (0x00)     |                            |
| 2       |                        | Length, LSB (0x0D)         |
| 3       | Message Type, MSB      |                            |
| 4       | Message Type, LSB      |                            |
| 5       | Reserved (0x00)        |                            |
| 6       | Sequence Number        |                            |
| 7       | Node ID                |                            |
| 8       | AIB ..                 | Address Method             |
| 9       |                        | Number of Address Elements |
| 10      |                        | Address Element Type       |
| 11      |                        | Data Length (0x04)         |
| 12      |                        | Data[0] – Slot Number      |
| 13      |                        | Data[1] – SIMM Number      |
| 14      | Checksum               |                            |

**Example 1**

The table below shows the *ARP Cache Query* message, with an AIB inside it. You would refer to the Slot AE for its format.

| MESSAGE (White) |                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------|
| Byte            | Field Description                                                                                   |
| 0               | Frame (0xFE)                                                                                        |
| 1, 2            | Length (0xNNNN)                                                                                     |
| 3, 4            | Message Type (0x00FC)                                                                               |

| :               | Data (TLVs)<br>0x01DC VoIP Module<br>0x01DD Flush ARP Cache Table Entry                             |
| :               | Checksum                                                                                            |

**Example 2 - Individual AEs Method – Two Address Elements**

The table below shows an AIB that uses the Individual AEs address method and that has two Address Elements. This AIB would be used in the *Connect* message, where:

- Address Element 1 defines Channel A
- Address Element 2 defines Channel B

| MESSAGE (White) |                       |
|-----------------|-----------------------|
| Byte            | Field Description     |
| 0               | Frame (0xFE)          |
| 1, 2            | Length (0x0011)       |
| 3, 4            | Message Type (0x0000) |
| 5               | Reserved (0x00)       |
| 6               | Sequence Number       |
| 7               | Logical Node ID       |

|   |                                                   |
|---|---------------------------------------------------|
| : | <u>AIB</u><br>Address Method<br>0x00 - Individual |

|   | AEs<br>0x0D Channel A<br>0x0D Channel B           |
| : | Checksum                                          |

### Example 2 - Range Method

The table below shows an example of an AIB that uses the Range address method. This AIB would be used in configuration messages to address a range of channels or other components, where:

- Address Element 1 defines the Starting Channel
- Address Element 2 defines the Ending Channel.

A range must contain **two and only two** Address Elements.

**Important!** To address a single channel using the range method, enter the same channel as both the starting and ending channel.

| MESSAGE (White) |                                                         |
|-----------------|---------------------------------------------------------|
| Byte            | Field Description                                       |
| 0               | Frame (0xFE)                                            |
| 1, 2            | Length (0xNNNN)                                         |
| 3, 4            | Message Type (0x00D3)                                   |
| 5               | Reserved (0x00)                                         |

## Address Elements

---

### 0x00 00 00 00 Null

| Byte | AIB Field Description |
|------|-----------------------|
| 2    | Address Element: 0x00 |
| 3    | Data Length 0x00      |

### 0x00 00 Null

Used in the *Matrix Configure*, *Matrix Query*, *System Configuration Query*, and *Virtual Card Configure* messages.

| Byte | AIB Field Description                       |
|------|---------------------------------------------|
|      | There are no additional fields for this AE. |

### 0x01 Slot

| Byte | AIB Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2    | Address Element: 0x01                                                                                                                                                                                                                                                                                                                                                                                                                                         |

\* Some API messages such as the *Line Card Switchover* message require two AEs as follows:

| Byte | AIB Field Description        |
|------|------------------------------|
| 2    | Address Element: 0x01        |
| 3    | Data Length 0x01             |
| 4    | Data[0] Starting Slot Number |

| Byte | AIB Field Description      |
|------|----------------------------|
| 5    | Address Element 0x01       |
| 6    | Data Length 0x01           |
| 7    | Data[0] Ending Slot Number |

## Slot Numbering

The tables below show the slot numbering schemes for the front and back of the CSP chassis.

### Front Slot Numbering, CSP

| Front Slots    | Power Cards | Line Cards |      |      |      |      |      |      |      | Matrix Cards | Fan Tray |
|----------------|-------------|------------|------|------|------|------|------|------|------|--------------|----------|
| Chassis Label  | Power2      | 15         | 14   | 13   | 12   | 11   | 10   | 9    | 8    | CPU2         | 0x16     |
| Software (Hex) | 0x11        | 0x0F       | 0x0E | 0x0D | 0x0C | 0x0B | 0x0A | 0x09 | 0x08 | 0x21         | 0x10     |
| Chassis Label  | Power1      | 7          | 6    | 5    | 4    | 3    | 2    | 1    | 0    | CPU1         |          |
| Software (Hex) | 0x12        | 0x07       | 0x06 | 0x05 | 0x04 | 0x03 | 0x02 | 0x01 | 0x00 | 0x20         |          |

### Back Slot Numbering, CSP

| Back Slots     | Matrix I/Os | Redundant or Standby Line Card I/Os |      |      |      |      |      |      |      |
|----------------|-------------|-------------------------------------|------|------|------|------|------|------|------|
| Chassis Label  | CPU1        | 0                                   | 1    | 2    | 3    | 4    | 5    | 6    | 7    |
| Software (Hex) | 0x14        | 0x30                                | 0x31 | 0x32 | 0x33 | 0x34 | 0x35 | 0x36 | 0x37 |
| Chassis Label  | CPU2        | 8                                   | 9    | 10   | 11   | 12   | 13   | 14   | 15   |
| Software (Hex) | 0x15        | 0x38                                | 0x39 | 0x3A | 0x3B | 0x3C | 0x3D | 0x3E | 0x3F |

**0x06 ISDN Call Reference**

| Byte | AIB Field Description |                |
|------|-----------------------|----------------|
| 2    | Address Element: 0x06 |                |
| 3    | Data Length:          | 0x04           |
| 4    | Data[0]               | Slot Number    |
| 5    | Data[1]               | Profile        |
| 6    | Data[2]               | Subrate        |
| 7    | Data[3]               | Call Reference |

**0x08 SS7 Stack**

| Byte | AIB Field Description |          |
|------|-----------------------|----------|
| 2    | Address Element: 0x08 |          |
| 3    | Data Length:          | 0x01     |
| 4    | Data[0]               | Stack ID |

**0x09 SS7 Link**

To address an SS7 signaling link, use the SS7 Link Address Element:

| Byte | AIB Field Description |          |
|------|-----------------------|----------|
| 2    | Address Element: 0x09 |          |
| 3    | Data Length:          | 0x02     |
| 4    | Data[0]               | Stack ID |
| 5    | Data[1]               | Link ID  |

**0x0C Logical Span**

| Byte | AIB Field Description |                            |
|------|-----------------------|----------------------------|
| 2    | Address Element:      | 0x0C                       |
| 3    | Data Length:          | 0x02                       |
| 4, 5 | Data[0, 1]            | Logical Span ID (MSB, LSB) |

**0x0D Channel**

| Byte | AIB Field Description |                            |
|------|-----------------------|----------------------------|
| 2    | Address Element:      | 0x0D                       |
| 3    | Data Length           | 0x03                       |
| 4, 5 | Data[0, 1]            | Logical Span ID (MSB, LSB) |
| 6    | Data[2]               | Channel                    |

**0x0E EXS Host-Slave Node**

| Byte | AIB Field Description |                                            |
|------|-----------------------|--------------------------------------------|
| 2    | Address Element       | 0x0E                                       |
| 3    | Data Length           | 0x01                                       |
| 4    | Data[0]               | Logical Node ID (Host Node: 0x000 - 0x1F)  |
| 5    | Address Element       | 0x0E                                       |
| 6    | Data Length           | 0x01                                       |
| 7    | Data[0]               | Logical Node ID (Slave Node: 0x000 - 0x1F) |

**0x10 Logical/Physical Node**

| Byte | AIB Field Description |      |
|------|-----------------------|------|
| 2    | Address Element       | 0x10 |
| 3    | Data Length:          | 0x05 |

| Byte | AIB Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4-7  | <p>Data[0-3]      Physical Node ID (4 Bytes)</p> <p>Enter the hexadecimal value of the last four digits of the serial number on the chassis or EXNET-ONE card. For the CSP 2090 and CSP 2040, you can find the last four digits on the rear of the CSP.</p> <p><b>EXNET Connect</b><br/>Because EXNET Connect is a card within a PC chassis, you assign the physical node ID by:</p> <p>Using the serial number of the EXNET Connect card for the last four digits of the serial number.</p> <p>Set the two most significant bytes to 0x0001.</p> <p>If the serial number of the user's EXNET Connect card was 0x03AD, in the Assign Logical Node ID message (0x10) define the value of the Physical Node ID field as 0x000103AD.</p> |
| 8    | <p>Data[4]      Logical Node ID</p> <p>Enter the ID you are assigning to the node. The default logical node ID of any CSP is 0xFF.</p> <p>When you use message 0x0010 to assign a logical node ID to a node, you must use the value 0xFF in the Logical Node ID field in the message header. The new logical ID is the value of Byte 8 in the AIB.</p> <p>To reassign a logical node ID, you must bring the EXNET ring out of service.</p>                                                                                                                                                                                                                                                                                            |

| 5    | Data[1]               | Physical Span<br><br><b>NOTE:</b> When you use this AIB for Loop Timing on the EXNET-ONE or EXNET Connect card, this field represents the span offset number of the span to be the loop timing source. To derive timing from the EXNET ring, the Physical Span Number is not used. |

**0x14 SS7 CIC Group**

In this AIB, the fields define a CIC Group by assigning a span/channel as the Base CIC for the group, and by defining the number of channels in the group. The remaining channels in the group are assigned CIC numbers in sequence. All the CICs in a group must be on the same span.

| Byte | AIB Field Description |                                                                                                                             |
|------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| 2    | Address Element:      | 0x14                                                                                                                        |

**0x29 Router**

In the *Route Control* message, to use the internal router to find a destination channel, use the Router address type. Currently, the Router Handle is always 0xFFFE.

| Byte | AIB Field Description    |
|------|--------------------------|
| 2    | Address Element: 0x29    |
| 3    | Data Length: 0x02        |
| 4, 5 | Data[0, 1] Router Handle |

**0x2A SS7 Subsystem Number**

| Byte | AIB Field Description         |
|------|-------------------------------|
| 2    | Address Element: 0x2A         |
| 3    | Data Length: 0x03             |
| 4    | Data[0] Stack ID              |
| 5    | Data[1] SCCP Subsystem Number |
| 6    | Data[2] 0x00 (Reserved)       |

**0x2C V5 ID**

If this AIB is used, the user port ID must be specified in a V5 Subscriber ID ICB (0x28). In the *PPL Event Indication* message this AIB and the Channel (0x0D) AIB are used for the V5 Layer 3P PSTN protocol. The V5 Configure and V5 Configuration Query messages also use this AIB.

| Byte | AIB Field Description |
|------|-----------------------|
| 2    | Address Element: 0x2C |
| 3    | Data Length 0x02      |
| 4    | Data[0] V5 ID (MSB)   |
| 5    | Data[1] V5 ID (LSB)   |

**0x2D V5 ID, Link ID**

The V5 ID, Link ID address type is used for Link blocking and unblocking.

| Byte | AIB Field Description |
|------|-----------------------|
| 2    | Address Element: 0x2D |
| 3    | Data Length 0x03      |
| 4    | Data[0] V5 ID (MSB)   |
| 5    | Data[1] V5 ID (LSB)   |
| 6    | Data[2] Link ID       |

**0x2F V5 Interface ID, User Port**

The V5 Interface ID, User Port address type is used for the following PPL Events: User Port Status Request and V5 Subscriber Query.

| Byte | AIB Field Description |                       |
|------|-----------------------|-----------------------|
| 2    | Address Element:      | 0x2F                  |
| 3    | Data Length           | 0x04                  |
| 4    | Data[0]               | V5 Interface ID (MSB) |
| 5    | Data[1]               | V5 Interface ID (LSB) |
| 6    | Data[2]               | User Port (MSB)       |
| 7    | Data[3]               | User Port (LSB)       |

**0x30 V5 Interface ID, User Port, Link, Timeslot**

| Byte | AIB Field Description |                       |
|------|-----------------------|-----------------------|
| 2    | Address Element:      | 0x30                  |
| 3    | Data Length           | 0x06                  |
| 4    | Data[0]               | V5 Interface ID (MSB) |
| 5    | Data[1]               | V5 Interface ID (LSB) |
| 6    | Data[2]               | Link ID               |
| 7    | Data[3]               | Timeslot              |
| 8    | Data[4]               | User Port (MSB)       |
| 9    | Data[5]               | User Port (LSB)       |

**0x31 SS7 Virtual CIC**

| Byte  | AIB Field Description |               |
|-------|-----------------------|---------------|
| 2     | Address Element:      | 0x31          |
| 3     | Data Length:          | 0x07          |
| 4     | Data[0]               | Stack ID      |
| 5-8   | Data[1-4]             | DPC (4 Bytes) |
| 9, 10 | Data[5, 6]            | CIC           |

**0x32 DS3 Offset**

| Byte | AIB Field Description |                         |
|------|-----------------------|-------------------------|
| 2    | Address Element:      | 0x32                    |
| 3    | Data Length:          | 0x02                    |
| 4    | Data[0]               | Slot Number             |
| 5    | Data[1]               | Offset                  |
|      |                       | This value is always 0. |

**0x36 MCC**

The MCC Group and Channel components use the MCC address type. Currently, the MCC is always 0xFFFE.

| Byte | AIB Field Description |        |
|------|-----------------------|--------|
| 2    | Address Element:      | 0x36   |
| 3    | Data Length:          | 0x02   |
| 4, 5 | Data[0, 1]            | Handle |

**0x3A D Channel Data Link Connection Identifier**

| Byte | AIB Field Description            |
|------|----------------------------------|
| 2    | Address Element: 0x3A            |
| 3    | Data Length: 0x04                |
| 4    | Data[0] Slot of ISDN card        |
| 5    | Data[1] D-Channels Offset (0-31) |
| 6    | Data[2] SAPI                     |
| 7    | Data[3] TEI                      |

**0x3C Number of CICS**

| Byte | AIB Field Description                 |
|------|---------------------------------------|
| 2    | Address Element: 0x3C                 |
| 3    | Data Length: 0x04                     |
| 4, 5 | Data[0, 1] Logical Span ID (MSB, LSB) |
| 6    | Data[2] Channel                       |
| 7    | Data[3] Number of Channels            |

**0x3D Ring Configuration Query**

Use the Ring Configuration Query AIB to query ring configuration.

**Important!** If you attempt to query the ring configuration while another query is in progress, the *Response Status* will be 0x3F (Ring Configuration Query Already in Progress)

| Byte | AIB Field Description                                                              |
|------|------------------------------------------------------------------------------------|
| 2    | Address Element: 0x3D                                                              |
| 3    | Data Length: 0x01                                                                  |
| 4    | Data[0] Slot Number of EXNET Card<br>(Enter 0xFF to query all rings in the system) |

**0x42 VoIP Module**

| Byte | AIB Field Description |             |
|------|-----------------------|-------------|
| 2    | Address Element: 0x42 |             |
| 3    | Data Length: 0x02     |             |
| 4    | Data[0]               | Slot Number |
| 5    | Data[1]               | Module      |

**0x45 Child Conference ID**

Use this AIB to create a Child Conference using the *Resource Create* message. The Child Conference ID should be set to 0xFFFF. The AIB in the response to the *Resource Create* message will contain the Parent Conference ID as well as the Child Conference ID, which is allocated by the CSP.

Use this AIB to connect to a Child Conference with the *Resource Connect* message. Indicate the actual Child Conference ID.

| Byte | AIB Field Description |                      |
|------|-----------------------|----------------------|
| 2    | Address Element: 0x45 |                      |
| 3    | Data Length: 0x04     |                      |
| 4, 5 | Data[0]               | Parent Conference ID |
| 6, 7 | Data[1]               | Child Conference ID  |

**0x48 Ring Communication Link**

This AIB enables synchronizing of an isolated node with a server node in an SS7/EXS multi-node system. If a node gets isolated for a period of time, any changes occurring on that node while it was in isolation get synchronized with the server node. This AIB takes out-of-service (OOS) the ring communication (RCOMM) link between the SS7 in the server node (that controls the remote CICs) and the remote node. An in-service (INS) message will re-establish the link. Messages should be sent to the SS7 server node only. Entry from both ACTIVE and STANBY matrix and SS7 are removed using only one *Service State Configure*. This AIB is only used in *Service State Configure*.

**Important!** Since this is a brute force mechanism to re-initialize the link, it should be used only rarely. SS7 application tasks are not informed about this link de-configuration so they behave as though the node is still accessible. This AIB should be used only when

there are no calls and no configuration. It should also be used in a pair of OOS and INS.

| Byte | AIB Field Description          |
|------|--------------------------------|
| 2    | Address Element: 0x48          |
| 3    | Data Length: 0x02              |
| 4    | Stack ID                       |
| 5    | Logical Node ID of remote node |

### 0x52 IP Signaling Series 3 Card ID or Expanded Logical Node ID

This AIB is generic. It can be used in any of the newer (introduced in 8.0 and above) Configure and Query messages for any component. If you use this AIB in the *IP Signaling Series 3 Card Configure* message (0x0100) you must also use AIB 0x53.

| Byte | AIB Field Description                                                                                                                                                                                                                                                                                                                   |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 4    | Data[0, 1] Expanded Logical Node ID<br><br>This field addresses the node/IP Signaling Series 3 Card ID and is used by the host application to route the messages to the proper node/ IP Signaling Series 3 Card. Logical Node ID in the header is ignored (it is set to 0xFE) and Expanded Logical Node ID is used to address the node. |

### 0x53 Object Type

This AIB is generic. It can be used in any Configure and Query message introduced in Release 8.0 and above to configure and query any component. The Object Type field indicates the type of object to be configured, and the Object Instance ID field indicates the ID of the particular instance of the Object in the Object Type field.

| Byte | AIB Field Description |
|------|-----------------------|
| 2    | Address Element: 0x53 |
| 3    | Data Length: 0x04     |

| Byte | AIB Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4    | Data[0, 1]      Object Type<br><br>This field indicates the type of object for which the configuration is meant. **0x64 Global Object Type**

The Global Object Type Address Element defines an object type such as a channel, span, or link. The object type list is common to all objects so no two objects in the system should have the same object type.

| Byte | Address Element Field Description |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**0x65 Global Object ID**

The Object ID Address Element always comes after an Object Type and defines a specific instance of the Object Type. Each object has to give the range of valid IDs it can support.

| Byte | AIB Field Description |                  |
|------|-----------------------|------------------|
| 0    | Address Element:      | 0x65             |
| 1    | Data Length:          | 0x02             |
| 2,3  | Data[0,1]             | Object ID Number |

**0x67 Functional Area**

Defines the part of the system affected by the message.

| Byte | Address Element Field Description |                    |
|------|-----------------------------------|--------------------|
| 2    | Address Element                   | 0x67               |
| 3    | Length                            | 0x02               |
| 4,5  | Data                              | 0x0001 - Signaling |

**0x73 IP Signaling Series 3 Card ID**

| Byte | AIB Field Description |                               |
|------|-----------------------|-------------------------------|
| 2    | Address Element:      | 0x73                          |
| 3    | Data Length:          | 0x02                          |
| 4    | Data[0, 1]            | IP Signaling Series 3 Card ID |

**0x7F SIP Stack ID**

| Byte | AIB Field Description |                                                                                                     |
|------|-----------------------|-----------------------------------------------------------------------------------------------------|
| 2    | Address Element:      | 0x7F                                                                                                |
| 3    | Data Length:          | 0x04                                                                                                |
| 4    | Reserved:             | 0xFF                                                                                                |
| 5    | Stack ID:             | 0x00                                                                                                |
| 6, 7 | Data [0,1]            | Call Handle. Tied to the Call ID. Used to address a particular SIP dialog. 0xFF 0xFF when querying. |

# 3 Information Control Blocks

## Overview

---

**Purpose** This chapter lists the Information Control Blocks (ICBs) used in the EXS API for the CSP. The ICBs are listed by type (Action, Data, and Extended Data). The Action ICBs are listed first, then the Data ICBs, and finally the Extended Data ICBs. Within each of these three sections, the ICBs are listed in hexadecimal numerical order.

# Introduction to ICBs

---

**Generic ICB Format**

The table below shows the generic format for an ICB.

|             |  |
|-------------|--|
| ICB Type    |  |
| ICB ID      |  |
| Data Length |  |
| Data[0]     |  |
| :           |  |

**ICB Type**

0x01 - Action

0x02 - Data

0x03 - Extended

**ICB Subtype**

The subtype defines the specific action the ICB performs, or the data it contains. The subtype values are defined in the ICB Subtype section of this chapter. In each API message that uses ICBs, the subtypes supported for that message are listed.

**Important!** Some Action ICB subtype values are used to indicate different ICBs, but they are unique within a particular message. For example, in the *Inseize Control* message, subtype 0x01 is the Report Call Processing Event ICB, while in the *Outseize Control* message, subtype 0x01 is the Scan For Wink N ICB.

Also, a specific ICB may have a different subtype value in different messages. For example, in the *Inseize Control* message, the Report Call Processing Event ICB is subtype 0x01, while in the *Outseize Control* message it is 0x04.

Make sure you use the proper ICB subtype value as defined in the specific API message. Data ICB subtypes are unique system-wide.

**ICB Data Length**

The length of the data to follow.

**ICB Data**

The data for each subtype is defined in the ICB Data section of this chapter, and in any API message which supports the subtype. Not all ICBs include data.

In each message, the data for each supported ICB is presented in the following format, if applicable:

|                 |
|-----------------|
| ICB Data Length |
| ICB Data [0]    |
| :               |

## Action ICBs

---

Most hex IDs are used to represent more than one Action ICB. Two or more ICBs with the same number are never used in the same API message. ICBs marked with an asterisk (\*) contain no data, so their data length is zero (0x00) and there is no table in this section.

| Hex  | Action ICB Name                                | Used in These Messages                                  |
|------|------------------------------------------------|---------------------------------------------------------|
| 0x00 | Null*                                          | <i>Inseize Control, Route Control, Outseize Control</i> |
| 0x01 | Free System Resources                          | <i>Connect With Data</i>                                |
|      | Report Call Processing Event                   | <i>Inseize Control</i>                                  |
|      | Scan For Wink N                                | <i>Route Control, Outseize Control</i>                  |
| 0x02 | Release Mode Configure                         | <i>Connect With Data</i>                                |
|      | Generate Call Processing Event                 | <i>Inseize Control</i>                                  |

| Data Length | 0x01                           |
| Data[0]     | Instruction Number (0x01–0x14) |

**0x0A Delay N Milliseconds**

See also 0x11, Delay N Milliseconds as used in the *Route Control* and *Outseize* messages

Delay values are measured in units of 10 milliseconds. The maximum delay value is 10 seconds (0x03E8).

Used in:

*Inseize Control* message

|             |                        |
|-------------|------------------------|
| ICB Type    | 0x01 (Action)          |
| ICB ID      | 0x0A or 0x11           |
| Data Length | 0x02                   |
| Data[0, 1]  | Delay Value (MSB, LSB) |

**0x0B Use Instruction List**

Used in:

*Route Control* message

*Outseize Control* message

|             |                                |
|-------------|--------------------------------|
| ICB Type    | 0x01 (Action)                  |
| ICB ID      | 0x0B                           |
| Data Length | 0x01                           |
| Data[0]     | Instruction Number (0x01–0x14) |

**0x10 Do Call Progress Analysis Without Line Signaling**

Used in:

*Route Control* message

*Outseize Control* message

|             |                                                                                                      |

**0x11 Delay N Milliseconds**

Delay values are measured in units of 10 milliseconds. The maximum delay value is 10 seconds (0x03E8).

Used in:

*Route Control* message

*Outseize Control* message

|             |                       |
|-------------|-----------------------|
| ICB Type    | 0x01 (Action)         |
| ICB ID      | 0x11                  |
| Data Length | 0x02                  |
| Data[0]     | Delay Value (2 Bytes) |

**0x35 Query Host Message Registration**

This query will return a list of API messages which the specified host is registered to receive (see Response Data).

Used in:

*Multi-Host Configure* message

|             |               |
|-------------|---------------|
| ICB Type    | 0x01 (Action) |
| ICB ID      | 0x35          |
| Data Length | 0x04          |
| Data[0-3]   | Host ID       |

**0x36 Query Host Connections**

Used in:

*Multi-Host Configure* message

|             |                                                             |
|-------------|-------------------------------------------------------------|
| ICB Type    | 0x01 (Action)                                               |
| ICB ID      | 0x36                                                        |
| Data Length | Variable                                                    |
| Data[0–3]   | Default Host ID (4 bytes)<br>(00 00 00 00 if not connected) |
| Data[4-5]   | Number of hosts connected<br>(2 bytes)                      |
| Data[6-9]   | Host ID 1 (4 bytes. First connected<br>additional host)     |
| Data[10-13] | Host ID 2 (4 bytes)                                         |
| :           | :                                                           |
| Data[:]     | Host ID N (4 bytes)                                         |

**0x37 Query Multi-Host Status**

Used in:

*Multi-Host Configure* message

|             |                                             |
|-------------|---------------------------------------------|
| ICB Type    | 0x01 (Action)                               |
| ICB ID      | 0x37                                        |
| Data Length | Variable                                    |
| Data[0–3]   | Default Host ID (4 bytes)                   |
| Data[4]     | Status<br>0x00 - Disabled<br>0x01 - Enabled |

**0x38 Query Hard-registered PPL Components**

This query will return a list of PPL components from which the specified host is registered to receive *PPL Event Indication* messages (see Response Data).

Used in:

*Multi-Host Configure* message

|             |               |
|-------------|---------------|
| ICB Type    | 0x01 (Action) |
| ICB ID      | 0x38          |
| Data Length | 0x04          |
| Data[0–3]   | Host ID       |

**0x39 Query Soft-registered PPL Components**

This query will return a list of PPL components from which the specified host is registered to receive *PPL Event Indication* messages (see Response Data).

Used in:

*Multi-Host Configure* message

|             |               |
|-------------|---------------|
| ICB Type    | 0x01 (Action) |
| ICB ID      | 0x39          |
| Data Length | 0x04          |
| Data[0–3]   | Host ID       |

**0x01 Stage N Address Data**

(Host-Supplied Digits)

Stage N Address Data ICBs use either host-supplied outpulsing or previously inpulsed digits. The format of the ICB depends on the type of digits you use.

The format of the Stage N Address Data ICB using host-supplied digits is as follows:

Used in:

*Route Control* message

*Outseize Control* message

### 0x11 ISDN Raw IEs

Any Raw IE can be inserted by the host for proprietary applications. Raw IEs will be inserted after any Formatted IEs (consult Q.931). The Q.931 recommendation specifies the format of the Raw IEs. IEs are always validated before issuing them in an ISDN message. The ISDN protocols ensure that the mandatory IEs are included with each ISDN message. See *ITU-T Q.931* for a list of valid Raw IEs.

Used in:

*Channel Release Request, Channel Released With Data, Release Channel with Data, Request For Service With Data, Route Control, Outseize Control, PPL Event Indication, PPL Event Request messages*

|             |                           |

| Data[0]     | State Number (0-255) |

**0x15 DASS2/DPNSS Raw Data**

The DASS2/DPNSS Raw Data ICB is a Raw DASS2/DPNSS frame that starts at the message/group octet (it does not include the address and control octets).

Used in:

*Route Control message*

*Outseize Control message*

|             |                                     |
|-------------|-------------------------------------|
| ICB Type    | 0x02 (Data)                         |

### 0x18 ISDN Raw IEs with Event

You can insert any valid IE into this ICB. The ISDN messages listed below have the listed IEs automatically inserted unless overridden by the host. All other messages have no IEs automatically inserted.

#### SETUP

- Call Reference (Formatted IE)
- Bearer Capability (Raw IE)
- Network-specific IE (Raw IE) (Unless B channel's Network Type is set to 1, see *B Channel Configure*)
- Channel ID (will always be inserted for Primary Rate, cannot be inserted by host)

#### RELEASE

- Cause (Formatted IE)

Used in:

*Connect with Data* message

|             |                      |
|-------------|----------------------|
| ICB Type    | 0x02 (Data)          |
| ICB ID      | 0x18                 |

| Data[5] | IE Data[0]                |

### 0x1A Call Type

Call Types:

0x0001 L3P Controlled

0x0002 Host Controlled

If the value of the Call Type field is 0x0001, the remaining data fields Data[2] through Data[n], represent the digits of the called party number.

The called party digits are noted in ASCII/IA5 format. For example, the digit “5” is indicated as 0x35.

If the value of the Call Type field is 0x0002, data fields Data[2] through Data[n] are not included in the ICB.

Used in:

*Route Control* message

*Outseize Control* message

|             |                    |
|-------------|--------------------|
| ICB Type    | 0x02 (Data)        |
| ICB ID      | 0x1A               |
| Data Length | Variable           |
| Data[0, 1]  | Call Type MSB, LSB |
| Data[2]     | Called Party Digit |
| Data[3]     | Called Party Digit |
| Data[4]     | Called Party Digit |

### 0x1C SS7 TUP Formatted Fields

Used in:

*Channel Release Request, Channel Released With Data, Connect With Data, Release Channel with Data, Route Control, Outseize Control, PPL Event Indication, PPL Event Request messages.*

|             |                                                                       |

| Data[:] | Field n Data Length (variable)                                        |
| Data[:] | Field n Data[0]                                                       |

### 0x1E Generic PPL

This ICB is used in various scenarios including call routing and establishing IP calls.

Used in:

*Route Control* message

*PPL Event Indication* message

*PPL Event Request* message

*Channel Release with Data* message

|             |                                       |

### 0x1F SS7 Unformatted Raw Parameters

This ICB is used to send the unrecognized message/message received on unequipped CIC from SPRC. The data bytes contain the entire ISUP message.

Used in:

*PPL Event Indication* message

## 0x22 Raw SS7 Data Parameters

This ICB is a general purpose one used to indicate different data formats. For example, it is used in the PPL event indications of CQS (Circuit Query Sending) to indicate local and remote status. Data definitions for this can be found in the *API Developer's Guide: Common Channel Signaling*. This ICB is also used by CVT (Circuit Validation Test) procedure for PPL event indications from component CVS (Circuit Validation Sending.). For more data information on this refer to the *Developer's Guide: Common Channel Signaling*, PPL Events.

| Data[n]     | :                                                      |

## 0x23 BT IUP Parameters

The BT IUP Parameters ICB (0x23) is used to transport any BT IUP Parameters message between the host and the CSP.

**Important!** In general, messages will contain one BT IUP ICB with one or more BT IUP TLVs.

|             |                                                                  |
|-------------|------------------------------------------------------------------|
| ICB Type    | 0x02 (Data)                                                      |
| ICB ID      | 0x23                                                             |
| Data Length | Variable                                                         |
| Data[0]     | Tag value corresponding to a unique element of a BT IUP message. |
| Data[1]     | Number of bytes to follow (usually 0x02)                         |
| Data[2]     | H0 (See following table.)                                        |
| Data[3]     | H1 (See following table.)                                        |
| Data[2+]    | Message Data                                                     |

## Message Types

The following table lists the messages in alphabetical order. The table also includes the H0 and H1 octets in binary code and the decimal code in brackets.

| Message Title                                            | Message Group Code (H0) | Message Type Code (H1) |
|----------------------------------------------------------|-------------------------|------------------------|

### 0x47 Enable Switch-Initiated Messages

Used in:

*Multi-Host Configure* message

|             |                                |
|-------------|--------------------------------|
| ICB Type    | 0x02 (Data)                    |
| ICB ID      | 0x47                           |
| Data Length | Variable                       |
| Data[0–3]   | Host ID                        |
| Data[4+]    | API Message 1 Type (Two bytes) |
| :           | :                              |
| :           | API Message n Type             |

### 0x48 Disable Switch-Initiated Messages

Used in:

*Multi-Host Configure* message

|             |                              |
|-------------|------------------------------|
| ICB Type    | 0x02 (Data)                  |
| ICB ID      | 0x48                         |
| Data Length | Variable                     |
| Data[0-3]   | Host ID                      |
| Data[4+]    | API Message 1 Type (2 bytes) |
| :           | :                            |
| :           | API Message n Type           |

### 0x49 Enable PPL Event Indication Messages

Used in:

*Multi-Host Configure* message

|             |                              |
|-------------|------------------------------|
| ICB Type    | 0x02 (Data)                  |
| ICB ID      | 0x49                         |
| Data Length | Variable                     |
| Data[0-3]   | Host ID                      |
| Data[4+]    | PPL Component ID 1 (2 bytes) |
| :           | :                            |
| :           | PPL Component ID n (2 bytes) |

**0x4A Disable PPL Event Indication Messages**

Used in:

*Multi-Host Configure* message

|             |                              |
|-------------|------------------------------|
| ICB Type    | 0x02 (Data)                  |
| ICB ID      | 0x4A                         |
| Data Length | Variable                     |
| Data[0-3]   | Host ID                      |
| Data[4+]    | PPL Component ID 1 (2 bytes) |
| :           | :                            |
| :           | PPL Component ID n (2 bytes) |

**0x4B Deregister Switch-Initiated Messages**

Used in:

*Multi-Host Configure* message

|             |                              |
|-------------|------------------------------|
| ICB Type    | 0x02 (Data)                  |
| ICB ID      | 0x4B                         |
| Data Length | Variable                     |
| Data[0-3]   | Host ID                      |
| Data [4+]   | API Message 1 Type (2 bytes) |
| :           | :                            |
| :           | API Message n Type           |

**0x4C Deregister PPL Components**

Used in:

*Multi-Host Configure* message

|             |                              |

| Data Length | 0x02                                       |
| Data[0-1]   | IP Signaling Series 3 Card ID<br>(2 bytes) |

**0x5D H.323 DTMF Signal Input Received**

A DTMF digit received from the PSTN or IP side of a call.

Used in:

*PPL Event Indication* message

|             |               |
|-------------|---------------|
| ICB Type    | 0x02 (Data)   |
| ICB ID      | 0x5D          |
| Data Length | 0x04          |
| Data[0-1]   | Digits        |
| Data[2-3]   | Duration (ms) |

**0x5E H.323 Signal Update Input Received**

A DTMF digit update received from PSTN or IP side of the call.

Used in:

*PPL Event Indication* message

|             |               |
|-------------|---------------|
| ICB Type    | 0x02 (Data)   |
| ICB ID      | 0x5E          |
| Data Length | 0x04          |
| Data[0-1]   | Digits        |
| Data[2-3]   | Duration (ms) |

**0x5F H.323 Alphanumeric Input Received**

An alphanumeric digit received from IP side of the call.

Used in:

*PPL Event Indication* message

|             |                      |
|-------------|----------------------|

## Extended Data ICBs

---

### 0x0012 SS7 Formatted Parameters

The SS7 Formatted Parameters Extended Data ICB supports Data greater than 255 bytes for call processing with ISUP messages.

For an SS7 channel in ANSI ISUP CRM/CRA, the *Outseize Control* message must include an SS7 Parameters ICB. This allows a CRM message type to be part of the SS7 Parameter ICB that is sent in the *Outseize Control* message. To send an IAM message after an *Outseize Control* message with CRM, a separate *PPL Event Request* for IAM must be made.

Used in:

*Outseize Control* message

*Request for Service with Data* message

*PPL Event Request* message

*PPL Event Indication* message

|                       |                                               |

**0x002C V5 User Port Range**

This ICB is used for call processing messages to and from Layer 3.

Used in:

*PPL Event Indication* message

*PPL Event Request* message

|                           |                                       |

| ICB ID                    | 0x002C                                |
| Data[1, 2]                |                                       |
| Data Length<br>Data[3, 4] | (0x00, 0x04), (2 Bytes)               |
| Data[5, 6]                | User Ports From (MSB, LSB), (2 Bytes) |
| Data[7, 8]                | User Port s To (MSB, LSB), (2 Bytes)  |

**0x002D Q.752 Parameter**

See MTP Parameter IDs from Q.752 for specific Parameter ID information. The format for the Q.752 Parameter is as follows:

Used in:

*PPL Event Indication* message

|                    |                                             |
|--------------------|---------------------------------------------|
| ICB Type           | 0x03 (Extended Data)                        |
| ICB ID             | 0x002D (Q.752 parameters)                   |
| ICB Length         | (2 Bytes) Length of parameters, in bytes    |
| Parameter 1 Type   | (2 Bytes) Parameter Type ID                 |
| Parameter 1 Length | (2 Bytes) Length of parameter data in bytes |
| Parameter 1 Value  | Variable size                               |
| :                  |                                             |
| Parameter n Type   | (2 Bytes) Parameter Type ID                 |
| Parameter n Length | (2 Bytes) Length of parameter data in bytes |
| Parameter n Value  | Variable                                    |

**0x002F V5 Statistics Query**

This ICB subtype is sent from the host using *PPL Event Request* message for Envelope Layer, LAPV, PSTN, BCC, Control Protocol, Protection Protocol, Link Protocol, and System Management Statistics. The Statistics return to the host in a *PPL Event Indication* message. After receiving V5 Statistics Query from the host, L3P Layer Manager sends a Positive Acknowledgment back to the host, indicating that L3P Layer Manager received the request.

Used in:

*PPL Event Request* message

*PPL Event Indication* message

|                           |                                      |
|---------------------------|--------------------------------------|
| ICB Type                  | 0x03 (Extended Data)                 |
| ICB ID<br>Data[1, 2]      | 0x002F                               |
| Data Length<br>Data[3, 4] | (0x00, 0x04), (2 Bytes)              |
| Data[5]                   | Query Type (0x01, 0x02)              |
| Data[6]                   | Query Subtype (0x00 - 0x09)          |
| Data[7]                   | Type (0x00 - 0x07)                   |
| Data[8, 9]                | C Channel No. or Port No. (MSB, LSB) |

### Query Types

0x01 V5 Statistics and zero statistics counters

0x02 V5 Statistics and don't zero statistics counters

### Query Subtypes

0x00 All Protocol Statistics

0x01 V5.2 ENVELOPE Layer Statistics

0x02 V5.2 LAPV Statistics

0x03 V5.2 PSTN Statistics

0x04 V5.2 CONTROL Protocol Statistics

0x05 V5.2 BCC Protocol Statistics

0x06 V5.2 LINK Protocol Statistics

0x07 V5.2 PROTECTION Protocol Data Link Statistics

0x08 V5.2 PROTECTION Protocol Interface Statistics

0x09 V5.2 SYSTEM MANAGEMENT Statistics

### Type

0x00 No Type

The following types are valid for V5.2 LAPV Statistics:

0x01 PSTN Data Link

0x02 BCC Data Link

0x03 CONTROL Data Link

0x04 LINK

0x05 PRIMARY PROTECTION Data Link

0x06 SECONDARY PROTECTION Data Link

**C Channel Number**

Valid for V5.2 ENVELOPE Layer Statistics and V5.2 PROTECTION Protocol Statistics:

0x00 Primary C Channel

0x01 Secondary C Channel

**Port Number**

User port number, and is valid for V5.2 SYSTEM MANAGEMENT Statistics.

**0x0030 V5 Statistics Data**

Used in:

*PPL Event Indication* message

|             |                       |
|-------------|-----------------------|
| ICB Type    | 0x03 (Extended Data)  |
| ICB ID      | 0x0030                |
| Data[1, 2]  |                       |
| Data Length | (MSB, LSB), (2 Bytes) |
| Data[3, 4]  |                       |
| Data[5]     | Data[0]               |
| Data[6]     | Data[1]               |
| :           | :                     |
| Data[N+3]   | Data[N]               |

The following statistics values are sent to the host in the ICB Data:

Data[0] = Query Subtype

Query Subtypes:

0x00 All Protocol Statics

0x01 V5.2 ENVELOPE Layer Statistics

0x02 V5.2 LAPV Statistics

0x03 V5.2 PSTN Statistics

0x04 V5.2 CONTROL Protocol Statistics

0x05 V5.2 BCC Protocol Statistics

0x06 V5.2 LINK Protocol Statistics

0x07 V5.2 PROTECTION Protocol Data Link Statistics

0x08 V5.2 PROTECTION Protocol Interface Statistics

0x09 V5.2 SYSTEM MANAGEMENT Statistics

Each data Variable is 4 Bytes long.

Data[1] means Data[1,2,3,4] bytes

**Query Subtype 0: For All Protocols**

Data for PSTN Protocol Statistics:

|          |                                                    |
|----------|----------------------------------------------------|
| Data[1]  | Number of Establish messages transmitted           |
| Data[5]  | Number of Establish ack messages transmitted       |
| Data[9]  | Number of Signal messages transmitted              |
| Data[13] | Number of Signal acknowledge messages transmitted  |
| Data[17] | Number of Status messages transmitted              |
| Data[21] | Number of Status enquiry messages transmitted      |
| Data[25] | Number of Disconnect messages transmitted          |
| Data[29] | Number of Disconnect complete messages transmitted |
| Data[33] | Number of Protocol parameter messages transmitted  |
| Data[37] | Number of Establish messages received              |
| Data[41] | Number of Establish ack messages received          |
| Data[45] | Number of Signal messages received                 |
| Data[49] | Number of Signal acknowledge messages received     |
| Data[53] | Number of Status messages received                 |
| Data[57] | Number of Status enquiry messages received         |
| Data[61] | Number of Disconnect messages received             |
| Data[65] | Number of Disconnect complete messages received    |
| Data[69] | Number of Protocol parameter messages received     |
| Data[73] | Total connections established so far               |
| Data[77] | Number of currently active connections             |

Data for Control Protocol Statistics:

|          |                              |
|----------|------------------------------|
| Data[81] | Port control transmitted     |
| Data[85] | Port control ack transmitted |

Data[89] Common control transmitted  
Data[93] Common control ack transmitted  
Data[97] Port control received  
Data[101] Port control ack received  
Data[105] Common control received  
Data[109] Common control ack received

Data for BCC Protocol Statistics:

Data[113] Allocation messages transmitted  
Data[117] Allocation messages received  
Data[121] Deallocation requests transmitted  
Data[125] Decollating requests received  
Data[129] Allocation rejects transmitted  
Data[133] Allocation rejects received  
Data[137] Allocation complete transmitted  
Data[141] Allocation complete received  
Data[145] Deallocation complete transmitted  
Data[149] Deallocation complete received  
Data[153] Audit transmitted  
Data[157] Audit received  
Data[161] Audit complete transmitted  
Data[165] Audit complete received  
Data[169] Fault transmitted  
Data[173] Fault received  
Data[177] Fault ack transmitted  
Data[181] Fault ack received

Data[185] Protocol error transmitted

Data[189] Protocol error received

Data for LINK Protocol Statistics:

Data[193] Number of Link Control transmitted

Data[197] Number of Link Control received

Data[201] Number of Link Control Ack transmitted

Data[205] Number of Link Control Ack received

Data for PROTECTION Protocol Data Link:  
(Statistics for Primary C Channel)

Data[209] Number of messages transmitted

Data[213] Number of messages received

Data for PROTECTION Protocol Data Link:  
(Statistics for Secondary C Channel)

Data[217] Number of messages transmitted

Data[221] Number of messages received

Data for PROTECTION Protocol Interface Statistics:

Data[225] Number of Switchover request transmitted

Data[229] Number of Switchover request received

Data[233] Number of Switchover command transmitted

Data[237] Number of Switchover command received

Data[241] Number of Operator initiated switchover command  
transmitted

Data[245] Number of Operator initiated switchover command  
received

Data[249] Number of Switchover ack transmitted  
Data[253] Number of Switchover ack received  
Data[257] Number of Switchover reject transmitted  
Data[261] Number of Switchover reject received  
Data[265] Number of Reset sequence number command transmitted  
Data[269] Number of Reset sequence number command received.  
Data[273] Number of Reset sequence number ack transmitted  
Data[277] Number of Reset sequence number ack received  
Data[281] Number of Protocol error transmitted  
Data[285] Number of Protocol error received

Data for SYSTEM MANAGEMENT Statistics:

Data[289] Number of times the ISDN port status T1 timer expired

**Query Subtype 1: V5.2 ENVELOPE Layer Statistics:**

Data[1] Number of Information frames transmitted  
Data[5] Number of Information frames received  
Data[9] Number of frames dropped

**Query Subtype 2: V5.2 LAPV Statistics:**

Data[1] Information frames transmitted  
Data[5] Receive ready frames transmitted  
Data[9] Receive not ready frames transmitted  
Data[13] Reject frames transmitted  
Data[17] Set asynchronous balanced mode frames transmitted  
Data[21] Unnumbered acknowledge frames transmitted  
Data[25] Disconnect mode frames transmitted  
Data[29] Information frames transmitted

Data[33] Receive ready frames transmitted  
Data[37] Receive not ready frames transmitted  
Data[41] Reject frames received  
Data[45] Set asynchronous balanced mode frames received  
Data[49] Unnumbered acknowledge frames received  
Data[53] Disconnect mode frames received  
Data[57] Invalid frames received  
Data[61] Set asynchronous balanced mode errors

**Query Subtype 3: V5.2 PSTN Statistics:**

Data[1] Number of Establish messages transmitted  
Data[5] Number of Establish ack messages transmitted  
Data[9] Number of Signal messages transmitted  
Data[13] Number of Signal acknowledge messages transmitted  
Data[17] Number of Status messages transmitted  
Data[21] Number of Status enquiry messages transmitted  
Data[25] Number of Disconnect messages transmitted  
Data[29] Number of Disconnect complete messages transmitted

Data[57] Number of Status enquiry messages received  
Data[61] Number of Disconnect messages received  
Data[65] Number of Disconnect complete messages received

Data[69] Number of Protocol parameter messages received

Data[73] Total connections established so far

Data[77] Number of currently active connections

**Query Subtype 4: V5.2 CONTROL Protocol Statistics:**

Data[1] Port control transmitted

Data[5] Port control ack transmitted

Data[9] Common control transmitted

Data[13] Common control ack transmitted

Data[17] Port control received

Data[21] Port control ack received

Data[25] Common control received

Data[29] Common control ack received

**Query Subtype 5: V5.2 BCC Protocol Statistics:**

Data[1] Allocation messages transmitted

Data[5] Allocation messages received

Data[9] Deallocation requests transmitted

Data[13] Decollating requests received

Data[17] Allocation rejects transmitted

Data[21] Allocation rejects received

Data[25] Allocation complete transmitted.

Data[29] Allocation complete received

Data[33] Deallocation complete transmitted

Data[37] Deallocation complete received

Data[41] Audit transmitted

Data[45] Audit received

Data[49] Audit complete transmitted

Data[53] Audit complete received

Data[57] Fault transmitted

Data[61] Fault received

Data[65] Fault ack transmitted

Data[69] Fault ack received

Data[73] Protocol error transmitted

Data[77] Protocol error received

**Query Subtype 6: V5.2 LINK protocol Statistics:**

Data[1] Number of Link Control transmitted

Data[5] Number of Link Control received

Data[9] Number of Link Control Ack transmitted

Data[13] Number of Link Control Ack received

**Query Subtype 7: V5.2 PROTECTION Protocol Datalink Statistics:**

Data[1] Number of messages transmitted

Data[5] Number of messages received

**Query Subtype 8: V5.2 PROTECTION Protocol Interface:**

Data[1] Number of Switchover request transmitted

Data[5] Number of Switchover request received

Data[9] Number of Switchover command transmitted

Data[13] Number of Switchover command received

Data[17] Number of Operator initiated switchover command transmitted

Data[21] Number of Operator initiated switchover command received

Data[25] Number of Switchover ack transmitted

Data[29] Number of Switchover ack received

Data[33] Number of Switchover reject transmitted

Data[37] Number of Switchover reject received

Data[41] Number of Reset sequence number command transmitted

Data[45] Number of Reset sequence number command received

Data[49] Number of Reset sequence number ack transmitted

Data[53] Number of Reset sequence number ack received

Data[57] Number of Protocol error transmitted

Data[61] Number of Protocol error received

**Query Subtype 9: V5.2 SYSTEM MANAGEMENT Statistics:**

Data[1] Number of times the ISDN port status T1 timer expired

**0x0031 V5 Status Indication**

This ICB is sent from the CSP in a *PPL Event Indication* message for specifying the V5 Status Indications.

Used in:

*PPL Event Indication* message

### 0x0033 NPDI Universal ICB

The *Route Control* message is sent with the following ICB to obtain a span/channel for an incoming call. This ICB is required for IP and Interworking calls.

The NPDI SIP Response Code TLV (0x2915) appears in this ICB when it is used in the *Channel Released with Data* message and *Release Channel with Data* messages. This ICB is required for the VDAC-ONE and IP Network Interface Series 2 cards.

This ICB is required to support Frequency Shift Keying for the DSP Series 2 card.

Used in:

*Outseize Control* message

*PPL Event Indication* message

*PPL Event Request* message

*Route Control* message

*Connect with Data* message

*Request for Service with Data* message

*Channel Released with Data* message

*Release Channel with Data* message

## SS7 and ISDN Values

---

This section provides data values required for SS7 ICBs, including the following:

- SS7 Parameter IDs
- MTP Statistics Parameter IDs from Q.752

See “SS7 ISUP Message Format Configure 0x6B” for a list of ISUP Message IDs.

### SS7 Parameter IDs

The following is a partial list of SS7 parameters. For a complete list and coding, consult the appropriate ANSI or ITU specification.

|      |                                   |
|------|-----------------------------------|
| 0x03 | Access transport                  |
| 0x27 | Automatic congestion level        |
| 0x11 | Backward call indicators          |
| 0xC6 | Business group                    |
| 0x01 | Call reference                    |
| 0x04 | Called party number               |
| 0x0A | Calling party number              |
| 0x09 | Calling party's category          |
| 0xC5 | Carrier identification            |
| 0xEE | Carrier selection information     |
| 0x12 | Cause indicators                  |
| 0xEB | Charge number                     |
| 0x0D | Connection request                |
| 0xC3 | Egress service                    |
| 0x07 | Forward call indicators           |

**MTP Parameter IDs from  
Q.752**

Parameter length for each ID listed below is 0x0004 except where noted.

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0000 | <p>MTP3 Timestamp</p> <p>This value is a 1msec resolution, modulus <math>2^{32}</math> timestamp derived from the internal processing logic of MTP3. The datum of this timestamp is established internally by each MTP3 at the time the signalling stack is configured and cannot be set.</p> <p>As presented, the timestamp should only be used for relative timing of MTP3 Q.752 events and reports within a signaling stack. The timestamp for interval reports identify the time associated with the end of the reporting interval and not the time of the actual report. Consequently, host attempts to correlate the timestamp to a time datum must consider only the 1<sup>st</sup> interval report of a sequence for this correlation.</p> |
| 0x0001 | <p>Interval sequence number</p> <p>This value is a modulus <math>2^{32}</math> sequence number which identifies the reporting interval. The initial value for the first reporting interval following start or restart of interval reporting is 1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**ISDN Values**

This section provides data values required for ISDN ICBs, including:

- Information Elements
- IE Fields
- Cause Codes

Parameter length for each ID listed below is 0x0004 except where noted.

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0000 | MTP3 Timestamp<br>This value is a 1msec resolution, modulus $2^{32}$ timestamp derived from the internal processing logic of MTP3. The datum of this timestamp is established internally by each MTP3 at the time the signalling stack is configured and cannot be set.<br>As presented, the timestamp should only be used for relative timing of MTP3 Q.752 events and reports within a signaling stack. The timestamp for interval reports identify the time associated with the end of the reporting interval and not the time of the actual report. Consequently, host attempts to correlate the timestamp to a time datum must consider only the 1 <sup>st</sup> interval report of a sequence for this correlation. |
| 0x0001 | Interval sequence number<br>This value is a modulus $2^{32}$ sequence number which identifies the reporting interval. The initial value for the first reporting interval following start or restart of interval reporting is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Information Elements**

Formatted IEs with Event include IE data fields. The data included in the format depends on the IE type. The data fields for each IE type is listed below. For more information on IE field values, refer to the *API Developer's Guide: Common Channel Signaling*.

**0x01 Call Reference**

The only length that is supported is 2:

Data[0] Most Significant Byte  
 Data[1] Least Significant Byte

**0x02 Called Party Number**

Data[0] Type of Number  
 Data[1] Numbering Plan Identification  
 Data[2] Number of Digits (maximum is 28)  
 Data[3–N] Number Digits (IA5/ASCII)

**0x03 Calling Party Number**

Data[0] Type of Number  
 Data[1] Numbering Plan Identification  
 Data[2] Presentation Indicator

Data[3] Screening Indicator  
Data[4] Number of Digits (maximum is 28)  
Data[5–N] Number Digits (IA5/ASCII)

**0x04 Called Party Subaddress**

Data[0] Type of Subaddress  
Data[1] Number of Digits (maximum is 28)  
Data[2–N] Number Digits (IA5/ASCII)

**0x05 Calling Party Subaddress**

Data[0] Type of Subaddress  
Data[1] Number of Digits (maximum is 28)  
Data[2–N] Number Digits (IA5/ASCII)

**0x06 Redirecting Number**

Data[0] Number Type  
Data[1] Numbering Plan  
Data[2] Presentation Indicator  
Data[3] Screening Indicator  
Data[4] Reason for Redirection  
Data[5] Number of Digits  
Data[6–N] Number Digits (IA5/ASCII)

**0x07 Cause**

Data[0] Coding Standard  
Data[1] Location  
Data[2] Recommendation  
Data[3] Cause Value  
Data[4] Diagnostics Length  
Data[5–N] Diagnostics Data

**0x08 Progress Indicator**

Data[0] Coding Standard  
Data[1] Location  
Data[2] Progress Description

**0x09 User-to-User**

Data[0] Protocol Discriminator  
Data[1–N] User Data

**0x0A Codeset 6**

Data[0] Raw IE Type  
Data[1] Raw IE Length  
Data[2–N] Raw IE Data  
IE types are network- and protocol-specific.

**0x0B Codeset 7**

Data[0] Raw IE Type  
Data[1] Raw IE Length  
Data[2–N] Raw IE Data  
IE types are network- and protocol-specific.

**0x11 Codeset 5**

The format for this IE is as follows:

Data[0] Raw IE Type  
Data[1] Raw IE Length  
Data[2–N] Raw IE Data  
IE types are network- and protocol-specific.

**0x12 Vari-A-Bill**

Data[0] Invoke\_ID (A unique identifier that specifies the feature request.)  
Data[1] Billing Type (If the billing type is “Free call,” you do not need to include the billing data.)  
Data[2] Hundreds  
Data[3] Tens  
Data[4] Ones  
Data[5] Tenths  
Data[6] Hundredths

**Bearer Capability**

You must represent this field as a Raw IE. Refer to Page 3-35 for the format and the Q.931 specification for values.

**Network-specific Facilities**

You must represent this field as a Raw IE. Refer to Page 3-35 for the format and the Q.931 specification for values.

**0x13 Directory Number (DN) Provisioning**

Data[0] Number of Digits in DN (n)  
 Data[1] Digit 0  
 Data[2] Digit 1  
 :  
 Data[n] Digit n  
 Data[n+1] B Channel Access:  
     Bit 0 Access to B1  
     Bit 1 Access to B2  
     Bit 2 Access to B1 and B2  
     Bits 3-7 Reserved, must be 0x00

**V5 Information Elements** V5 formatted IEs with Event include IE data fields. The data included in the format depends on the IE type. The data fields for each IE type are listed below. For more information on IE field values, refer to the *Developer's Guide: Common Channel Signaling*.

**V5 PSTN IEs 0x01 Pulse Notification**

Data[0] Type 0x01  
 Data[1] Length 0x00

**0x02 Line Information**

Data[0] Type 0x02  
 Data[1] Length 0x01  
 Data[2] Parameter

**0x03 State**

Data[0] Type 0x03  
 Data[1] Length 0x01  
 Data[2] PSTN FSM State

**0x04 Autonomous Signaling Sequence**

Data[0] Type 0x04  
 Data[1] Length 0x01  
 Data[2] Sequence Type

**0x05 Sequence Response**

Data[0] Type 0x05  
Data[1] Length 0x01  
Data[2] Sequence Response Value

**0x06 Reserved****0x07 Cadence Ringing**

Data[0] Type 0x07  
Data[1] Length 0x01  
Data[2] Cadence Ringing Type

**0x08 Pulsed Signal**

Data[0] Type 0x08  
Data[1] Length 0x01 or 0x05  
Data[2] Pulse Type  
Data[3] Pulse Duration Type (Optional)  
Data[4] Suppression Indicator (Optional)  
Data[5] Number of Pulses (Optional)  
Data[6] Acknowledge Request Indicator (Optional)

**0x09 Steady Signal**

Data[0] Type 0x09  
Data[1] Length 0x01  
Data[2] Steady Signal Type

**0x0A Digit Signal**

Data[0] Type 0x0A  
Data[1] Length 0x02  
Data[2] Digit Acknowledge Request Indicator  
Data[3] Digit Information

**0x0B Recognition Time**

Data[0] Type 0x0B  
Data[1] Length 0x02  
Data[2] Signal  
Data[3] Duration Time

**0x0C Pulsed Signal**

|         |                                                                                    |              |

**Parameter Type Values for Cadence Ringing Extended IE**

|      |                          |
|------|--------------------------|
| 0x02 | CLIP CLI (Digits)        |
| 0x04 | CLIP RAI (No Digits)     |
| 0x07 | CNIP CNI (Characters)    |
| 0x08 | CNIP RAN (No Characters) |

The Cadence Ringing Extended IE can be encoded one of the following ways (A, B, C, or D)

**0x10            Cadence Ringing Extended  
(Type A - Digits and Characters Present)**

Data[0]    Type    0x10  
 Data[1]    Length  
 Data[2]    Cadence Ringing Type  
 Data[3]    Month (binary)  
 Data[4]    Day (binary)  
  
 Data[5]    Hour (binary)  
  
 Data[6]    Minute (binary)  
 Data[7]    CLIP CLI Parameter Type 0x02  
 Data[8]    CNIP CNI Parameter Type 0x07  
 Data[9]    Number of Digits in Calling Party  
  
 Data[10]   Calling Party Digit 1 (ASCII)  
 Data[11]   Calling Party Digit 2 (ASCII)  
  
 :            :  
 Data[N - 1]   Calling Party Digit N  
 Data[N]       Number of Characters in Calling Party  
 Data[N + 1]   Character 1  
 Data[N + 2]   Character 2  
 Data[N + M]   Character M

**0x10    Cadence Ringing Extended  
(Type B - Digits Present, Characters Missing )**

Data[0]    Type    0x10  
 Data[1]    Length  
 Data[2]    Cadence Ringing Type  
 Data[3]    Month (binary)  
 Data[4]    Day (binary)  
  
 Data[5]    Hour (binary)  
  
 Data[6]    Minute (binary)  
 Data[7]    CLIP CLI Parameter Type 0x02  
 Data[8]    CNIP RAN Parameter Type 0x08  
 Data[9]    Number of Digits in Calling Party  
  
 Data[10]   Calling Party Digit 1 (ASCII)  
 Data[11]   Calling Party Digit 2 (ASCII)

:                   :  
 Data[N - 1] Calling Party Digit N  
 Data[N] Reason for Absence of CNIP

**0x10 Cadence Ringing Extended  
 (Type C - Digits Missing, Characters Present)**

Data[0] Type 0x10  
 Data[1] Length  
 Data[2] Cadence Ringing Type  
 Data[3] Month (binary)  
 Data[4] Day (binary)  
  
 Data[5] Hour (binary)  
  
 Data[6] Minute (binary)  
 Data[7] CLIP RAI Parameter Type 0x04  
 Data[8] CNIP CNI Parameter Type 0x07  
 Data[9] Reason for Absence of Digits  
  
 Data[10] Number of Characters in Calling Party  
  
 Data[11] Calling Party Digit 2 (ASCII)  
           Character 1  
           Character 2  
           Character M

**0x10 Cadence Ringing Extended  
 (Type D - Digits and Characters Missing)**

Data[0] Type 0x10  
 Data[1] Length  
 Data[2] Cadence Ringing Type  
 Data[3] Month (binary)  
 Data[4] Day (binary)  
  
 Data[5] Hour (binary)  
  
 Data[6] Minute (binary)  
 Data[7] CLIP RAI Parameter Type 0x04  
 Data[8] CNIP RANParameter Type 0x08  
           Reason for Absence of Digits\*  
           Reason for Absence of Characters\*

\*Reason for Absence Values:

0x4F Unavailable  
 0x50 Private

**0x11 Reserved****0x12 Called Party**

Data[0] Type 0x0E  
 Data[1] Length N  
 Data[2] Digit Acknowledge Request Indicator  
 Data[3] Number of Digits  
 Data[4] Digit[0] ASCII  
  
 Data[5] Digit[1] ASCII  
  
 : :  
 Data[N+5] Digit[N] ASCII

**V5 BCC IEs****0x15 User Port ID IE**

Data[0] Type 0x15  
 Data[1] Length 0x02  
 Data[2] User Port (MSB)  
 Data[3] User Port (LSB)

**0x17 V5 Timeslot ID IE**

Data[0] Type 0x17  
 Data[1] Length 0x03  
 Data[2] Link ID  
 Data[3] V5 Timeslot Number  
 Data[4] Override (0 or 1)

**0x1B V5 Timeslot ID IE**

Data[0] Type 0x1B  
 Data[1] Length 0x01  
 Data[2] Reason  
     0x00 Incomplete Normal  
     0x01 AN Fault  
     0x02 User port Not Provisional  
     0x03 Invalid V5 Timeslot  
     0x04 Invalid V5 Link ID  
     0x05 Timeslot used as C Channel

**IE Fields**

The list below shows the field values used in the ISDN Information Elements.

**Billing Type**

0x90 New Rate  
0x91 Flat Rate  
0x93 Premium Charge  
0x94 Premium Credit  
0x98 Free Call

**Coding Standard**

0x00 ITU-T  
0x02 National Standard Coding  
0x03 Standard Specific

**Location**

0x00 User  
0x01 Private Network serving local user  
0x02 Public Network serving local user  
0x03 Transit Network  
0x04 Public Network Serving Remote User  
0x05 Private Network Serving Remote User  
0x07 International Networks  
0x0A Network Beyond Interworking Point

**Number Plan Identification**

0x00 Unknown  
0x01 ISDN Numbering Plan/Recommendation E.164/E.163  
0x02 Telephony numbering plan  
0x09 Private numbering plan

**Presentation Indicator**

0x00 Presentation is allowed  
0x01 Presentation is restricted  
0x02 Number not available due to interworking

**Progress Indicator**

0x00 Unknown  
0x01 Not End to End ISDN (In-band Info)  
0x02 Destination Address Not ISDN  
0x03 Origination Address Not ISDN  
0x04 Call has Returned to the ISDN  
0x08 In-band Information Available

**Reason For Redirection**

0x00 Unknown  
 0x01 Call Forward Busy  
 0x02 Call Forward No Answer  
 0x05 Called DTE Out of order  
 0x0A Call Forward by Called DTE  
 0x0F Unconditional Call Forwarding

**Recommendation**

0x00 Q.931  
 0x03 X.21  
 0x04 X.25

**Screening Indicator**

0x00 User-provided, not screened  
 0x01 User-provided, verified and passed  
 0x02 User-provided, verified and failed  
 0x03 Network-provided

**Type of Number**

0x00 Unknown  
 0x01 International number  
 0x02 National number  
 0x04 Subscriber number  
 0x06 Abbreviated number

**Cause Codes**

This section lists all the Cause codes included in clearing messages (*Disconnect*, *Release*, *Release Complete*) and in error messages (*Status*).

For details on the cause code values, refer to Table I.2 in the Q.931 specification.

|    |                                                                                                                                                                                           |
|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16 | Normal Call Clearing.<br>This is used in <i>Disconnect</i> if another cause is not specified in the clear request message.                                                                |
| 17 | User Busy                                                                                                                                                                                 |
| 30 | Response to <i>Status Query</i> message.                                                                                                                                                  |
| 34 | No channel available. This is used in <i>Release Complete</i> for rejecting <i>Setup</i> when no channel is available. The channel is indicated as preferred in the <i>Setup</i> message. |
| 41 | Temporary failure. This is used in <i>Disconnect</i> after channel purge because the host is not responding to the clear indication.                                                      |

|     |                                                                                                                                                                                                  |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 44  | Requested channel not available. This is used in <i>Release Complete</i> to reject <i>Setup</i> when the specified channel is not available. Channel is indicated as exclusive in <i>Setup</i> . |
| 65  | Bearer capability not implemented. This is used in <i>Release Complete</i> to reject a <i>Setup</i> with invalid Bearer Capability.                                                              |
| 96  | Mandatory Information Element missing.<br>Used in <i>Release Complete</i> or <i>Status</i> message                                                                                               |
| 98  | Invalid message type. This is used in the <i>Status</i> message.                                                                                                                                 |
| 100 | Invalid Information Element content. This is used in the <i>Status</i> message.                                                                                                                  |
| 102 | Recovery on timer expiration. This is used in <i>Release</i> or <i>Release Complete</i> after expiration of timers T305 and T308.                                                                |

## DASS2/DPNSS Values

---

This section provides data values required for DASS2/DPNSS ICBs, including the following:

- Information Elements
- Cause Codes

**Information Elements** DASS2/DPNSS information elements may be sorted in the IE Library using the *ISDN Interface Configure* message. You may access them with Atomic Function 95 from the PPL design document.

### 0x01 Service Indicator Code (SIC)

The only length that is supported is 2:

Data[0] Octet 1 of the Service Indicator Code

Data[1] Octet 2 of the Service Indicator Code (optional)

### 0x02 Selection Data

Data[0–N] per BTNR 190, Section 4 for DASS2  
and BTNR 188, Section 4 for DPNSS

### 0x03 Indication Data

Data[0–N] per BTNR 190, Section 4 for DASS2  
and BTNR 188, Section 4 for DPNSS

**Cause Codes** This sections lists all the Cause codes included in clearing messages (*Disconnect*, *Release*, *Release Complete*) and in error messages (*Status*).

For details on the cause code values, refer to Table I.2 in the Q.931 specification.

### DASS2

The following are DASS2 cause codes:

|   |                     |
|---|---------------------|
| 0 | Number Unobtainable |
| 1 | Address Incomplete  |

|    |                                           |
|----|-------------------------------------------|
| 2  | Network Termination                       |
| 3  | Service Unavailable                       |
| 4  | Sub Incompatible                          |
| 5  | Sub Changed Number                        |
| 6  | Invalid Request for Supplementary Service |
| 7  | Congestion                                |
| 8  | Subscriber Engaged                        |
| 9  | Sub Out of Service                        |
| 10 | Incoming Calls Barred                     |
| 11 | Outgoing Calls Barred                     |
| 18 | Remote Procedure Error                    |
| 19 | Service Incompatible                      |
| 20 | Acknowledgment                            |
| 21 | Signal Not Understood                     |
| 26 | Message Not Understood                    |
| 30 | NAE Error                                 |
| 31 | No Reply from Sub                         |
| 32 | Service Termination                       |
| 41 | Access Barred                             |
| 45 | DTE Controlled Not Ready                  |
| 46 | DTE Uncontrolled Not Ready                |
| 48 | Sub Call Termination                      |
| 50 | ET Isolated                               |
| 51 | Local Procedure Error                     |

## DPNSS

The following are DPNSS cause codes:

|    |                                 |
|----|---------------------------------|
| 0  | Number Unobtainable             |
| 1  | Address Incomplete              |
| 2  | Network Termination             |
| 3  | Service Unavailable             |
| 4  | Subscriber Incompatible         |
| 7  | Congestion                      |
| 8  | Busy                            |
| 9  | Subscriber Out of Service       |
| 10 | Incoming Calls Barred           |
| 19 | Service Incompatible            |
| 20 | Acknowledgment                  |
| 21 | Signal Not Understood           |
| 22 | Signal Not Valid                |
| 23 | Service Temporarily Unavailable |
| 24 | Facility Not Registered         |
| 25 | Reject                          |
| 26 | Message Not Understood          |
| 27 | Signaling System Incompatible   |

|    |                                       |
|----|---------------------------------------|
| 28 | Route Out of Service                  |
| 29 | Transferred                           |
| 30 | NAE (Network Address Extension) Error |
| 35 | Channel Out of Service                |
| 36 | Priority Forced Release               |
| 41 | Access Barred                         |
| 45 | DTE Controlled Not Ready              |
| 46 | DTE Uncontrolled Not Ready            |

# 4 Tag Length Value Blocks

## Overview

---

**Purpose** This chapter lists the Tag Length Value Blocks (TLVs) used in the EXS API for the CSP. The single-byte (0xNN) TLVs are first, listed in hexadecimal numerical order. They are followed by the double-byte (0xNNNN) TLVs, also listed in hexadecimal numerical order.

## Introduction to TLVs

---

In Call Control, the TLV is used to send data to, and receive data from, the CSP within API messages.

A TLV is an internal data structure consisting of the following elements:

- Tag - a label identifying the format of the TLV
- Length - the length of the data to follow
- Value - the data

### Generic TLV Format

The generic format of a TLV is shown below:

| Byte | Description     |
|------|-----------------|
| 1    | Tag (MSB)       |
| 2    | Tag (LSB)       |
| 3    | Length (MSB)    |
| 4    | Length (LSB)    |
| 5    | Value[0] (Data) |
| :    | :               |
| :    | Value[n]        |

**Nested TLVs** The Call Agent feature and the DSP/RTP feature use nested TLVs. The following provides an overview and example of nested TLVs. An API message can contain nested TLVs. These TLVs are nested into the value field of another TLV in order to capture multiple properties of a call within one TLV.

The following applies to these nested TLVs.

- The TLV Count fields in the API message accounts for the top level TLVs but not the nested TLVs.
- The same TLV can be used multiple times within the same message depending on the context of the nested TLVs.
- The Length field in any “parent” TLV counts the bytes in all of its nested TLVs.

**Example:**

```

69 00 43 00 EA 01
01 0D 03 00 12 06
 00 A7
 00 20
 01
 03
 00 33
 00 53
 00 01 \\Number of TLVs - top level
 29 FF 00 4D \\Parent TLV
Nested TLVs [2A 0E 00 04 D0 D1 2B 37
 2A 01 00 41\\Length includes all nested TLVs
Nested TLVs [2A 03 00 01 00
 2A 07 00 04 00 00 13 98
 2A 0A 00 02 00 14
 2A 02 00 13 \\Length includes next 3 TLVs
Nested TLVs [2A 08 00 02 00 02
 2A 09 00 01 02
 2A 0B 00 04 00 00 1F 40
 2A 02 00 13 \\Length includes next 3 TLVs
Nested TLVs [2A 08 00 02 01 65
 2A 09 00 01 32
 2A 0B 00 04 00 00 1F 40

```

DG\_Nested\_TLVs\_Example.vsd

**Interworking TLVs**

This chapter contains TLVs used for Interworking and are indicated as such. Some of these Interworking TLVs can also be used in Standard environments and that is indicated as well.

Refer to *Interworking* in the *Developer's Guide: Internet Protocol*.

Interworking TLVs are used in the following API messages:

**Host to CSP**

- *Outseize Control*
- *Route Control*
- *Inseize Control*
- *Connect with Data*
- *Release Channel with Data*
- *Outpulse Digits*
- *PPL Event Request*

**CSP to Host**

- *Request for Service with Data*
- *Channel Released with Data*
- *PPL Event Indication*
- *Channel Release Request*

## TLVs

---

### 0x01 Trunk Number

Used in:

*SS7 CLI Configure* message

| Byte | Description                                    |
|------|------------------------------------------------|
| 0    | Tag 0x01                                       |
| 1    | Length 0x04                                    |
| 2-5  | Value[0-3] Trunk Number (IA5/ASCII characters) |

### 0x01 Module, IP Address, and Subnet Mask

Use this TLV to configure the IP Address of a VoIP module.

In this TLV block, the module value (Data[0]) must change to reflect the IP address of the VoIP Module assigned. When IP addresses are re-assigned, the TCP/IP stack must be re-initialized. To ensure that the stack is re-initialized properly, you must reboot the board or module, using one of the following TLVs:

- Engage IP (0x02): If the Engage IP TLV is assigned, reset is automatic
- Reset (0x03)

Used in:

*IP Address Configure* message

*IP Address Query* message

| Byte | Description                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------|
| 0    | Tag 0x01 Module, IP Address, Subnet Mask                                                                                      |

**0x04 Reset Indicator**

At any time, the host can send a *Reset Configuration* message to the card to ensure that the IP address is assigned. The reset indicator value is returned in the Reset Indicator TLV. If the host sends a Reset or Engage TLV, an ACK is returned with all Indicator bits set to 0. If neither the Reset nor the Engage TLV is sent, the bit mask applies.

Used in:

*IP Address Configure* message

| Byte | Description                                                                                                                                                                                                                                                   |

### 0x05 Gateway IP

The host can assign Gateway IP addresses the following ways:

- to the main board alone
- to the main board and all modules together
- to individual modules

If the first data byte of the Gateway IP TLV specifies the main board and all modules together (0x05), then the message must have a TLV block for the main board and for each module, specifying their individual IP addresses and subnet masks.

**Important!** Data byte 0x05 cannot be used in conjunction with 2 module VDAC-ONE or IP Network Interface Series 2 cards. For a two module VDAC-ONE or IP Network Interface Series 2 card, you must assign the gateway address with each individual module IP address.

Used in:

- *IP Address Configure* message
- *IP Address Query* message

| Byte | Description                                                                                                                                                   |

| 3    | Value[1] Socket ID                       |

**0x07 Close Socket**

Used in:

*IP Socket Configure* message

| Byte | Description                              |
|------|------------------------------------------|
| 0    | Tag 0x07 Close Socket                    |
| 1    | Length 0x02                              |
| 2    | Value[0] 0x00 Module (0xFF = Main Board) |
| 3    | Value[1] Socket ID                       |

**0x08 Prohibit Traffic on Socket**

Used in:

*IP Socket Configure* message

| Byte | Description                              |
|------|------------------------------------------|
| 0    | Tag 0x08 Prohibit Traffic on Socket      |
| 1    | Length 0x02                              |
| 2    | Value[0] 0x00 Module (0xFF = Main Board) |
| 3    | Value[1] Socket ID                       |

**0x09 Allow Traffic on Socket**

Used in:

*IP Socket Configure* message

| Byte | Description                              |
|------|------------------------------------------|
| 0    | Tag 0x09 Allow Traffic on Socket         |
| 1    | Length 0x02                              |
| 2    | Value[0] 0x00 Module (0xFF = Main Board) |
| 3    | Value[1] Socket ID                       |

**0x09 Ethernet Link Redundancy**

Use this TLV to enable Ethernet Link Redundancy. If you enable Ethernet Link Redundancy, the lower Ethernet Port is automatically activated. Note that Ethernet Link Redundancy is not supported on the SS7 Series 3 card.

Used in:

*IP Address Configure* message

*IP Address Query* message

| Byte | Description                                        |
|------|----------------------------------------------------|
| 0    | Tag 0x09 Ethernet Link Redundancy                  |
| 1    | Length 0x04                                        |
| 2-5  | Value[0-3] 0x00000000 Disable<br>0x00000001 Enable |

**0x0A Activate Ethernet Port**

Use this TLV to assign the active Ethernet Port on a VDAC-ONE card. The upper port is active by default. To activate the lower port, you must send this TLV. Note that Ethernet Link Redundancy is not supported on the SS7 Series 3 card.

**Important!** If you enable Ethernet Link Redundancy (TLV 0x09), the standby Ethernet Port is automatically activated upon failure of the active port.

This TLV also activates the Ethernet Interface of the Maxtrix Controller I/O as follows:

- Activate the Upper Port for Ethernet Interface B.
- Active the Lower Port for Ethernet Interface A.

Used in:

*IP Address Configure* message

*IP Address Query* message

| Byte | Description                                                           |
|------|-----------------------------------------------------------------------|
| 0    | Tag 0x0A Activate Ethernet Port                                       |
| 1    | Length 0x04                                                           |
| 2    | Value[0] 0x00000000 Upper Port Active<br>0x00000001 Lower Port Active |

**Important!** The two TLVs above (0x09 and 0x0A) are returned in the response to a successful *IP Address Query* message.

**0x0A Socket Status**

Used in:

*IP Socket Status Report* message

| Byte | Description                                                                                                                                                                                       |

**0x0009 Address Element TLV**

**Important!** In the Address Element TLV, the *Resource Attribute Configure* message requires either the Expanded Span Channel AIB or the IP Address AIB, but not both. The Address Element Blocks TLV that follows can refer to either the Expanded Span/Channel AIB or to the IP Address AIB.

For Expanded Span/Channel AIB:

Use this TLV to address configuration to a specific channel. If you are changing the attributes of an existing connection, use the Channel address type (0x0D).

Used in:

*Resource Attribute Configure* message

| Byte | Description                                     |
|------|-------------------------------------------------|
| 0, 1 | Tag: Address Element (0x0009)                   |
| 2, 3 | Length: 0x0005                                  |
| 4    | Value[0] AIB Type: 0x0D (Expanded Span/Channel) |
| 5    | Value[1] AIB Length (0x03)                      |
| 6    | Value[2] Logical Span (MSB)                     |
| 7    | Value[3] Logical Span (LSB)                     |
| 8    | Value[4] Channel                                |

For IP Address AIB:

Use this TLV to address configuration to a specific VoIP module.

**Important!** This TLV is required for all attribute configuration except for Gateway Mode (Gateway Mode TLV, 0x01D0), which configures an entire IP Network Interface Series 2 card.

If you are pre-configuring the attributes on a VoIP module, use the IP Address type (0x3E).

Used in:

*Resource Attribute Configure* message

| Byte | Description                                |
|------|--------------------------------------------|
| 0, 1 | Tag: Address Element (0x0009)              |
| 2, 3 | Length: 0x0006                             |
| 4    | Value: Data[0] AIB Type: 0x3E (IP Address) |
| 5    | Value: Data[1] AIB Length 0x04             |
| 6-9  | Value: Data[2-5] IP Address (4 bytes)      |

**0x0009 Poll Interval**

The poll interval, which is in 10 milliseconds units, should be configured with values greater than 5. If configured with anything less than 5, the IP Signaling Series 3 card will automatically set the poll interval to 5.

**Important!** This poll is the Matrix to IP Signaling Series 3 card poll not the IP Signaling Series 3 card to Host poll.

Used in:

*Matrix Configure* message (0x7D)

| Byte | Description                                                                        |
|------|------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x0009                                                                         |
| 2, 3 | Length 0x0004                                                                      |
| 4, 5 | Value[0-1] Number of Seconds Between Polls 0x00 - 0xFF<br>In 10 milliseconds units |
| 6, 7 | Value[2-3] Number of Missed Polls Before Link is Declared<br>Down 0x00 - 0xFF      |

**0x0009 Terminating Channel**

Use this TLV to specify a destination channel or a node. This TLV is used for the Terminating Channel routing method. The span/channel or node are specified in the TLV in an Address Information Block (AIB).

Used in:

0x001E or 0x1E Generic PPL ICB in *Route Control* message

| Byte | Description                            |
|------|----------------------------------------|
| 0, 1 | Tag 0x0009 Terminating Channel or Node |
| 2, 3 | Length 0x0005                          |
| 4    | Value[0] AIB Type: 0x0D                |
| 5    | Value[1] AIB Length (0x03)             |
| 6    | Value[2] Logical Span (MSB)            |
| 7    | Value[3] Logical Span (LSB)            |
| 8    | Value[4] Channel                       |

**0x0009 Terminating Span/Channel, Single Address**

Used in:

*PPL Table Download (0x00D6)*

| Byte | Description      |
|------|------------------|
| 0, 1 | Tag 0x0009       |
| 2, 3 | Length 0x0006    |

| 0    | Tag 0x00 V5 C Channel Assignment (MSB)                                         |
| 1    | Tag 0x0A V5 C Channel Assignment (LSB)                                         |
| 2    | Length 0x00 (MSB)                                                              |
| 3    | Length 0x06 (LSB)                                                              |
| 4    | Type 0x01 = PG1 Primary<br>0x02 = PG1 Secondary<br>0x03 = PG#2 (Not Supported) |
| 5    | Logical Span ID for Primary Link, MSB                                          |
| 6    | Logical Span ID for Primary Link, LSB                                          |
| 7    | Primary Physical Channel 16                                                    |
| 8    | V5 C Channel ID 0x00 = Primary<br>0x01 - 0x2B = Others                         |
|      | Link ID                                                                        |

### 0x000B V5 Cpath Assignment

Used in:

*V5 Configure* message

*V5 Configuration Query* message

This TLV is currently not supported.

| Byte | Description                        |
|------|------------------------------------|
| 0    | Tag 0x00 V5 Cpath Assignment (MSB) |
| 1    | Tag 0x0B V5 Cpath Assignment (LSB) |
| 2    | Length 0x00 (MSB)                  |
| 3    | Length 0x02 (LSB)                  |
| 4    | C Channel ID                       |
| 5    | Cpath Type 0x00 = PSTN             |

Before adding a C path you must create a C Channel and the C Channel should belong to Protection Group 2. Protection Group 2 is not supported.

### 0x000B IP Signaling Series 3 Card Version

Used in:

*Matrix Configure* message (0x007D)

*Matrix Status Report* message

*Matrix Query* message (0x0097)

| Byte | Description             |
|------|-------------------------|
| 0, 1 | Tag 0x000B              |
| 2, 3 | Length 0x0006           |
| 4, 5 | Major Revision Variable |
| 6, 7 | Minor Revision Variable |
| 8, 9 | Build Number Variable   |

### 0x000C Matrix IP Address

Used in:

*IP Signaling Series 3 Card Configure* message (0x0100)

*IP Signaling Series 3 Card Query* message (0x0101)

| Byte | Description                     |

| 4    | V5 C Channel ID 0x00 = Primary<br>0x01 - 0x2B = Others |

**0x000F Link Down Timer**

This timer is used when the link between the IP Signaling Series 3 Card and the Matrix Controller goes down. If there is a secondary Matrix Controller present in the node, the IP Signaling Series 3 card triggers this timer and does not release any active calls (calls in the answered state). The IP Signaling Series 3 card waits until the timer expires to re-establish the connection with the secondary matrix.

If the connection is re-established, all the active calls stay connected; however, no new calls (incoming or outgoing) can be made when the link between the Matrix Controller and IP Signaling Series 3 card is temporarily down.

If the link is not re-established or if there is no secondary Matrix Controller in the node, all of the active calls are released on the H.323 (IP) end.

Used in:

*IP Signaling Series 3 Card Configure* message

*IP Signaling Series 3 Card Query* message

| Byte | Description                                                                                       |

### 0x0101 RTP Payload Size (VDAC-ONE)

By changing the multiple of the payload size, you can configure how much encoded PCM data a packet contains.

**Example:** For G.711, a 160-byte payload of encoded PCM data is sent at the G.711 Basic Packet Rate of every 20 milliseconds. But if you change the multiple for G.711 to 2x, then a 320-byte payload is sent every 40 milliseconds.

In effect, changing the multiple also changes the throughput available over an Ethernet network. Larger packets create greater network delay overall, but they use the Ethernet bandwidth more efficiently. Smaller packets may use the Ethernet bandwidth less efficiently, but they may provide better voice quality.

#### **0x0101 RTP Payload Size (IPN Series 2)**

RTP payload sizes can be changed in multiples of the specified RTP Payload Type's base packetization rate. On the IP Network Interface Series 2 card, the RTP payload size is tightly coupled with RTP payload type. Changing the default RTP payload type also changes the default RTP payload size to its applicable value (unless a new default RTP payload size is also specified). Using the non-default RTP Payload Type during call establishment results in the default RTP Payload Size not being used. If the RTP Payload Size is not provided, the default for the specific payload type is used.

In effect, changing the multiple also changes the throughput available over an Ethernet network. Larger packets create greater network delay overall, but they use the Ethernet bandwidth more efficiently. Smaller packets may use the Ethernet bandwidth less efficiently, but they may provide better voice quality.

| 2, 3 | Length      | 0x0001                                |
| 4    | Value[0]    | 0x00 Disable (Default)<br>0x01 Enable |

**0x0103 RTP Echo Cancellation**

Enables and disables Echo Cancellation

Used in:

0x1E and 0x001E Generic PPL ICBs in:

*Resource Attribute Query* message

*Resource Attribute Configure* message

| Byte | Description                                    |
|------|------------------------------------------------|
| 0, 1 | Tag 0x0103 RTP Echo Cancellation               |
| 2, 3 | Length 0x0001                                  |
| 4    | Value[0] 0x00 Disable<br>0x01 Enable (Default) |

**0x0104 RTP Packets Lost**

Indicates the number of RTP packets lost.

Used in:

*Channel Released with Data* message

| Byte | Description                                 |
|------|---------------------------------------------|
| 0, 1 | Tag 0x0104                                  |
| 2, 3 | Length 0x0004                               |
| 4-7  | Value[0-3] Number of Packets Lost (4 Bytes) |

**0x0105 RTP Packets Received**

Indicates the number of RTP packets received.

Used in:

*Channel Released with Data* message

| Byte | Description                                     |
|------|-------------------------------------------------|
| 0, 1 | Tag 0x0105                                      |
| 2, 3 | Length 0x0004                                   |
| 4-7  | Value[0-3] Number of Packets Received (4 Bytes) |

**0x0110 RTP Octets Received**

Indicates the number of RTP octets received.

Used in:

*Channel Released with Data* message

| Byte | Description                                   |
|------|-----------------------------------------------|
| 0, 1 | Tag 0x0110                                    |
| 2, 3 | Length 0x0004                                 |
| 4-7  | Value[0-3] Number of Octets Received(4 Bytes) |

**0x0111 RTP Packets Sent**

Indicates the number of RTP packets sent.

Used in:

*Channel Released with Data* message

| Byte | Description                                   |
|------|-----------------------------------------------|
| 0, 1 | Tag 0x0111                                    |
| 2, 3 | Length 0x0004                                 |
| 4-7  | Value[0-3] Number of Octets Received(4 Bytes) |

**0x0112 RTP Octets Sent**

Indicates the number of RTP octets sent.

Used in:

*Channel Released with Data* message

| Byte | Description                                |
|------|--------------------------------------------|
| 0, 1 | Tag 0x0112                                 |
| 2, 3 | Length 0x0004                              |
| 4-7  | Value[0-3] Number of Octets Sent (4 Bytes) |

**0x0115 Call Agent Mode**

Enables Call Agent Mode which allows bearer-free calls.

Used in:

*VoIP Protocol Configure* message

| Byte | Description |                                                                                       |
|------|-------------|---------------------------------------------------------------------------------------|
| 0, 1 | Tag         | 0x0115                                                                                |
| 2, 3 | Length      | 0x0001                                                                                |
| 4    | Value[0]    | Call Agent Mode:<br>0x00 - Disables Call Agent Mode<br>0x01 - Enables Call Agent Mode |

**0x0116 Channel Service TLV**

Indicates whether the connection being established will be switched through the CSP or will bypass the CSP.

For VoIP calls, if this TLV is not present in one of the messages listed below, a switched CSP connection is created.

For non-VoIP calls, this TLV is ignored and an CSP switched connection is created.

Used in:

0x1E Generic PPL ICB in:

*PPL Event Request* message

*Connect with Data* message

| Byte | Description |                                                                                                                                                                                                    |
|------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag         | 0x0116                                                                                                                                                                                             |
| 2, 3 | Length      | 0x0001                                                                                                                                                                                             |
| 4, 5 | Value[0-1]  | Bearer Service Mode:<br><br>0x0000 - Bearer-switched through the CSP which implies a physical span channel.<br><br>0x0001 - Bearer-free. The CSP is bypassed which implies a virtual span channel. |

**0x0117 Alerting Propagation Mode**

Use this TLV to indicate whether or not to suppress the automatic generation of the alerting signal by the CSP when the connected remote party sends out an alerting signal to the CSP. This TLV is for the SIP 180 message.

Used in:

0x1E Generic PPL ICB in:

*PPL Event Request* message

*Connect with Data* message

| Byte | Description                                                          |
|------|----------------------------------------------------------------------|
| 0, 1 | Tag 0x0117                                                           |
| 2, 3 | Length 0x0001                                                        |
| 4    | Value[0] 1 Suppress alerting<br>2 Do not suppress alerting (default) |

### 0x0118 Companding Conversion Mode

Use this TLV to specify whether PCM encoding format conversion should be bypassed or not. The default is 0 in which case PCM encoding format is not bypassed. A value of 1 bypasses the conversion process and forces the B side of the call leg to use the A side's companding format.

Used in:

0x1E and 0x001E Generic PPL ICBs in:

*Route Control* message

*Connect with Data* message

| Byte | Description                                                                                  |
|------|----------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x0118                                                                                   |
| 2, 3 | Length 0x0001                                                                                |
| 4    | Value[0] 0x00 Companding Conversion enabled (default)<br>0x01 Companding Conversion disabled |

### 0x0119 Media Offer Stage

Use this TLV with the Alerting or Progress call processing event to ask for a media connection before the Answer message is sent.

Used in:

0x1E Generic PPL ICB in:

*PPL Event Request* message

| Byte | Description                                                    |
|------|----------------------------------------------------------------|
| 0, 1 | Tag 0x0119                                                     |
| 2, 3 | Length 0x0002                                                  |
| 4    | Value[0] 0x0000 - Do not offer media.<br>0x0001 - Offer media. |

**0x011A Call Agent Mode Physical Channel ID**

Used in:

0x1E Generic PPL ICB in:

*PPL Event Request* message

*Connect with Data* message

| Byte | Description                                      |
|------|--------------------------------------------------|
| 0, 1 | Tag 0x011A - Call Agent Mode Physical Channel ID |
| 2, 3 | Length 0x0003                                    |
| 4,5  | Value[0, 1] Span ID                              |
| 6    | Value[2] Channel ID                              |

**0x0141 Modify Connection**

Use this TLV to change the connection type of an established connection between two channels without having to park the channels during the transition. Add this TLV to the *Connect with Data* message along with the Connection Type TLV (0x0612). If you do not include the Connection Type TLV, the Modified Connection defaults to a two-way connection.

Used in:

0x1E Generic PPL ICB in:

*Connect with Data* message

| Byte | Description                                                  |
|------|--------------------------------------------------------------|
| 0, 1 | Tag 0x0141 Modify Connection                                 |
| 2, 3 | Length 0x0002                                                |
| 4,5  | Value[0, 1] 0x0000 - Apply changes unconditionally (default) |

**0x0168 VDAC Module IP Address**

Use this TLV to populate the Router Component (0x0064) with the VDAC module IP address.

Used in:

*PPL Table Download* message

| Byte | Description                          |
|------|--------------------------------------|
| 0, 1 | Tag 0x0168                           |
| 2, 3 | Length 0x0004                        |
| 4-7  | Value[0-3] IP Address of VDAC module |

**0x01AE Poll Interval Configure**

Use this TLV to specify the poll interval and the number of missed polls before a connection is declared down.

Used in:

*VoIP Protocol Query* message

*VoIP Protocol Configure* message

| Byte | Description                                                                  |
|------|------------------------------------------------------------------------------|
| 0, 1 | Tag 0x01AE                                                                   |
| 2, 3 | Length 0x0004                                                                |
| 4    | Value[0] Poll Interval, MSB: 0x00-0xFF                                       |
| 5    | Value[1] Poll Interval, LSB: 0x00-0xFF                                       |
| 6    | Value[2] Number of Missed Polls Before Link is Declared Down, MSB: 0x00-0xFF |
| 7    | Value[3] Number of Missed Polls Before Link is Declared Down, LSB: 0x00-0xFF |

**0x01C2 Minimum Jitter Buffer Delay**

The data in this TLV block are in millisecond units. The range of legitimate values is 0-150 milliseconds.

Used in:

0x1E and 0x001E Generic PPL ICBs in:

*Resource Attribute Query* message

*Resource Attribute Configure* message

| Byte | Description                            |
|------|----------------------------------------|
| 0, 1 | Tag 0x01C2 Minimum Jitter Buffer Delay |
| 2, 3 | Length 0x0001                          |
| 4    | Value[0] 0x00-0x96 ms (0x4B Default)   |

**0x01C3 Maximum Jitter Buffer Delay**

The data in this TLV block are in millisecond units. The range of legitimate values is 150-300 ms.

Used in:

0x1E and 0x001E Generic PPL ICBs in:

*Resource Attribute Query* message

*Resource Attribute Configure* message

| Byte | Description                                   |
|------|-----------------------------------------------|
| 0, 1 | Tag 0x01C3 Maximum Jitter Buffer Delay        |
| 2, 3 | Length 0x0004                                 |
| 4    | Value[0] 0x00                                 |
| 5    | Value[1] 0x00                                 |
| 6, 7 | Value[2, 3] 0x0096-0x012C<br>0x0096 (Default) |

### 0x01C4 Adaptation Rate

Use this TLV to configure the Adaption Rate on a VDAC-ONE card.

The data in this TLV block are in millisecond units. The range of legitimate values is 0-12 milliseconds.

Used in:

0x1E and 0x001E Generic PPL ICBs in:

*Resource Attribute Query* message

*Resource Attribute Configure* message

| Byte | Description                       |
|------|-----------------------------------|
| 0, 1 | Tag 0x01C4 Adaptation Rate        |
| 2, 3 | Length 0x0001                     |
| 4    | Value[0] 0x00-0x0C (0x07 Default) |

### 0x01C5 Fax Type Enable

If the fax type is set to Disable, then the fax will go through as a voice call. Therefore, the fax transmission might not be successful.

Used in:

0x1E Generic PPL ICB in:

*Resource Attribute Query* message

*Resource Attribute Configure* message

| Byte | Description                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x01C5 Fax Type Enable                                                                                                    |
| 2, 3 | Length 0x0001                                                                                                                 |
| 4    | Value[0] <b>ONE</b> of the following:<br>0x00 Disable (Default) - RTP not changed.<br>0x01 Enable Relay<br>0x02 Enable Bypass |

**0x01C6 Modem Enable Transport Method**

Used in:

0x1E Generic PPL ICB in:

*Resource Attribute Query* message

*Resource Attribute Configure* message

| Byte | Description                                                                                       |
|------|---------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x01C6 Modem Enable Transport Method                                                          |
| 2, 3 | Length 0x0001                                                                                     |
| 4    | Value[0] 0x00 Transparent Mode<br>0x01 Modem Relay Mode (not supported)<br>0x02 Modem Bypass Mode |

**0x01C7 Fax/Modem Bypass Coder Type**

Cantata recommends using G.711 A-Law or  $\mu$ -Law for fax/modem bypass mode.

Used in:

0x1E and 0x001E Generic PPL ICBs in:

*Resource Attribute Query* message

*Resource Attribute Configure* message

| Byte | Description    |                                     |                          |

**0x01C8 Protocol Type**

Use this TLV to specify the protocol used by the TLVs in the *VoIP Protocol Configure* and *VoIP Protocol Query* messages.

Used in:

0x1E Generic PPL ICB in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                      |
|------|--------------------------------------------------|
| 0, 1 | Tag 0x01C8                                       |
| 2, 3 | Length 0x0001                                    |
| 4    | Value[0] 0x04 SIP<br>0x05 H.323<br>0x06 RFC 2833 |

**0x01C9 Primary Matrix IP Port**

Use this TLV to specify the IP address and port number for the primary Call Agent. The port number must be greater than 0x0400 (1024).

Used in:

*VoIP Protocol Query* message

*VoIP Protocol Configure* message

| Byte | Description             |
|------|-------------------------|
| 0, 1 | Tag 0x01C9              |
| 2, 3 | Length 0x0006           |
| 4-7  | Value[0-3] IP Address   |
| 8, 9 | Value[1, 2] Port Number |

**0x01CA Secondary Matrix IP Port**

Use this TLV to specify the IP address and port number for the secondary Call Agent. The port number must be greater than 0x0400 (1024).

Used in:

*VoIP Protocol Query* message

*VoIP Protocol Configure* message

| Byte | Description                     |
|------|---------------------------------|
| 0, 1 | Tag 0x01CA                      |
| 2, 3 | Length 0x0006                   |
| 4-7  | Value[0-3] IP Address (4 bytes) |
| 8, 9 | Value[1, 2] Port Number         |

### 0x01D0 Gateway Mode

Use this TLV to configure an IP Network Interface Series 2 card to be in Gateway Mode or Normal Mode.

**Important!** This TLV is addressed to a card, and therefore cannot be combined in a message with any other TLVs.

Used in:

*Resource Attribute Configure* message

| Byte | Description                                                                                             |
|------|---------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: Gateway Mode (0x01D0)                                                                              |
| 2, 3 | Length: 0x0001                                                                                          |
| 4    | Value: Setting<br>0x01 Gateway Mode (Non-port Consuming Mode)<br>0x02 Normal Mode (Port Consuming Mode) |

### 0x01D1 RTP Payload Redundancy

Use this TLV to set the redundancy packet depth for RTP at configuration time. You can also set the RTP packet depth in real time, using an *Outseize Control* or *Route Control* message.

Used in:

0x1E Generic PPL ICB in:

*Resource Attribute Query* message

*Resource Attribute Configure* message

| Byte | Description                                                      |
|------|------------------------------------------------------------------|
| 0, 1 | Tag: 0x01D1 RTP Payload Redundancy                               |
| 2, 3 | Length: 0x0001                                                   |
| 4    | Value[0] 0x00 No Redundancy (Default)<br>0x01 Redundancy Level 1 |

**0x01D2 Fax Payload Redundancy**

Use this TLV to set the redundancy packet depth for Fax at configuration time only.

Used in:

0x1E Generic PPL ICB in:

*Resource Attribute Query* message

*Resource Attribute Configure* message

| Byte | Description                                                                                                                                                                                                                                |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x01D2 Fax Packet Depth                                                                                                                                                                                                               |
| 2, 3 | Length: 0x0001                                                                                                                                                                                                                             |
| 4    | Value[0] <b>ONE</b> of the following:<br>0x00 No Redundancy (Default)<br><br>0x01 Redundancy Level 1<br><br>0x02 Redundancy Level 2<br>(VDAC-ONE card maximum)<br><br>0x03 Redundancy Level 3<br>(IP Network Interface Series 3 card only) |

**0x01D4 Type of Service**

Use this TLV to set the quality of service for outgoing packets (RTP/RTCP/T.38). This attribute can be modified in a run-time environment.

Note that the signaling protocol is responsible to adhere to the RFC Standards when imposing type of service restrictions.

Used in:

0x1E Generic PPL ICB in:

*Resource Attribute Configure* message

*Resource Attribute Query* message

| Byte | Description                   |
|------|-------------------------------|
| 0, 1 | Tag: Type of Service (0x01D4) |
| 2, 3 | Length: 0x0001                |

|   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 0x01D6 DNS IP Address

Use this TLV to configure the DNS lookup in the Matrix Controller card. Use 0x00000000 if the Secondary or Tertiary DNS IP address is not used.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte  | Description                  |
|-------|------------------------------|
| 0, 1  | Tag 0x01D6                   |
| 2, 3  | Length 0x000C                |
| 4-7   | Value[0-3] Primary DNS IP    |
| 8-11  | Value[4-7] Secondary DNS IP  |
| 12-15 | Value [8-11] Tertiary DNS IP |

**0x01D7 Default Domain Name**

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                           |
|------|-------------------------------------------------------|
| 0, 1 | Tag 0x01D7                                            |
| 2, 3 | Length Variable                                       |
| :    | Value Null-terminated ASCII string for default domain |

**0x01DB Connection Mode**

Use this TLV to set the connection mode. A line can be connected to receive only, transmit only, or both.

Used in:

*Resource Attribute Configure* message

*Resource Attribute Query* message

| Byte | Description                                                                                                                                                                                                                                                                                                                                                                     |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag Connection Mode (0x01DB)                                                                                                                                                                                                                                                                                                                                                    |
| 2, 3 | Length 0x0001                                                                                                                                                                                                                                                                                                                                                                   |
| 4    | Value[0] <ul style="list-style-type: none"> <li>0x00 Two-way connection</li> <li>0x01 One-way listen/receive only</li> <li>0x02 One-way talk/transmit only</li> <li>0x03 Hold connection. No voice is transmitted or received.</li> <li>0xFF (Default)</li> </ul> You see this value only if you query the default settings of a VoIP module or when the call is not connected. |

**0x01DC VoIP Module**

Use this TLV to indicate a VoIP module.

Used in:

0x00FB *ARP Cache Report* message

| Byte | Description            |
|------|------------------------|
| 0, 1 | Tag 0x01DC VoIP Module |
| 2, 3 | Length 0x0001          |
| 4    | Value[0] Module Number |

**0x01DD Flush ARP Cache Table Entry**

Send this TLV to remove entries from an ARP Cache table. You must also include a VoIP Module TLV to indicate the module.

To remove all entries in the table, enter a length of 0x0000.

To remove an entry for a specific IP address, enter a length of 0x0004 and enter the IP address in Data[4-7].

To remove an entry for a specific Ethernet address, enter a length of 0x0006 and enter the Ethernet address in Data[4-9].

Used in:

*ARP Cache Query*

| Byte | Description                                                                                                                                                                                                                                                                    |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0,1  | Tag Flush ARP Cache Table Entry (0x01DD)                                                                                                                                                                                                                                       |
| 2, 3 | Length Variable (see below)                                                                                                                                                                                                                                                    |
| 4    | Value:0x0000<br>To remove all entries on the module.<br>There is no data.<br>0x0004<br>To remove a specific IP address.<br>Also enter the IP address in Data[4-7].<br>0x0006<br>To remove all entries at an Ethernet Address.<br>Also enter the Ethernet address in Data[4-9]. |

**0x01DE ARP Cache Table Entry**

This TLV is used in the *ARP Cache Report* message to report the IP Address and Ethernet Address for an entry in the ARP Cache table. Separate TLVs are sent for each entry in the table.

| Byte  | Description                      |
|-------|----------------------------------|
| 0, 1  | Tag 0x01DE ARP Cache Table Entry |
| 2, 3  | Length 0x000E                    |
| 4-7   | Value[0-3] Entry Number          |
| 8-11  | Value[4-7] IP Address            |
| 12-17 | Value[8-13] Ethernet Address     |

**0x01DF    UDP Source Port Validate**

Use this TLV to enable a VoIP media stream to be checked for its validity by authenticating the UDP source port of the incoming packets. The default value is 1 and implies that the UDP source port validation is performed on the received packets. By setting the value of this TLV to 1, the UDP source port field in every received packet (whether RTP, RTCP or T.38 packet) is validated.

Used in:

0x1E Generic PPL ICB in:

*Resource Attribute Configure* message

*Resource Attribute Query* message

**0x01E0    ARP Cache Report Information**

This TLV is sent in the *ARP Cache Report* message to indicate the number of messages required for the report and the number of the current message.

| Byte | Description                                           |
|------|-------------------------------------------------------|

| 3    | Value[1]   Current Message Number                     |

**0x01E1    Fax Compatibility Mode**

Use this TLV to determine the VDAC-ONE card's T.38 Fax Relay Compatibility Mode:

- Backward Compatible mode

or

- Interoperability mode.

These modes are incompatible. You can choose one mode or the other, but not both. The Backward Compatible mode is interoperable with the fax relay mode on the previously-released software. The Interoperability Mode is primarily used to interoperate with third party T.38 fax relay.

This TLV can be configured only before the call is established. It cannot be configured during an active call. This TLV does not apply to the IP Series 2 card.

#### **0x01E2 RFC 2833 Enable**

Use this TLV to allow the in-band DTMF signals to be relayed within the VoIP media stream utilizing a special RTP payload type. Low bit-rate audio codecs (such as G.729 or G.723.1) can compromise the signal integrity of DTMF digits (and other telephony tones and signals); hence causing inaccurate and poor detection/recognition of the DTMF digits at the recipient side. When this feature is enabled the incoming DTMF digits, if detected, are removed from the audio stream by the VDAC-ONE or IP Network Interface Series 2 card connected to the originator of the DTMF digits. The information regarding the detected and removed DTMF digits is embedded within the RTP stream using a special payload format. The VDAC-ONE or IP Network Interface Series 2 card at the receiving side will decode this special RTP payload that carries DTMF digits and regenerate the DTMF signal toward the receiving PSTN side.

If you are using the VDAC-ONE card, this TLV can be configured only before or during the call establishment. It cannot be set during an active call. If you are using the IP Networking Series 2 card, this TLV can be configured while the call is active.

**Important!** The CSP does NOT support RFC 2833 via H.323 signaling.

### 0x01E5 VoIP Resource Profile Assign

The Resource Profile Assign (0x01E5) TLV has been created to configure a module's resource profile. Similar to changing the Gateway Mode, changing a VoIP module resource profile causes its TDM resources to change, causing the IP Network Interface Series 2 card to reset, so that new resources can be allocated.

**Important!** Changing the resource profile on any module causes the IP Network Interface Series 2 card host configuration to be reset.

You cannot mix VoIP resource profiles on the same IP Network Interface Series 2 card or in the same chassis.

The Resource Profile Assign (0x01E5) TLV addresses the VoIP module by its module number. Since updating a VoIP module's profile causes the IP Network Interface Series 2 card to reset, all of the modules can be reset in a single message.

The host has the flexibility to send one VoIP Resource Profile Assign TLV to assign the same resource profile to all modules or send multiple TLVs to individual modules. If any TLV is invalid, the message is negatively acknowledged (NACKED) and no action is taken.

Used in:

*Resource Attribute Configure* message

#### **0x01E6 Source T.38 Port**

Use this TLV to specify the local T.38 port number for the fax relay. This TLV can be set on-the-fly. There is no default value for this TLV (i.e., no default T.38 port will be assumed). Therefore is imperative for the Host to resolve this port number as early as possible to ensure the proper fax relay operation. If this port number is not specified (in time), the fax relay will fail.

Used in:

0x1E Generic PPL ICB in:

*Resource Attribute Configure* message

*Route Control* message

*Outseize Control* message

| Byte | Description           |
|------|-----------------------|
| 0, 1 | Tag 0x01E6            |
| 2, 3 | Length 0x0002         |
| 4, 5 | Value[0, 1] T.38 Port |

#### **0x01E7 Destination T.38 Port**

Use this TLV to specify the remote T.38 port number for the fax relay. This TLV can be set on-the-fly. There is no default value for this TLV (i.e., no default T.38 port will be assumed). Therefore is imperative for the Host to resolve this port number as early as possible to ensure the proper fax relay operation. If this port number is not specified (in time), the fax relay will fail.

Used in:

| 2, 3 | Length 0x0002         |
| 4, 5 | Value[0, 1] T.38 Port |

### 0x01E8 Source RTCP Port

Use this TLV to specify the local RTCP port number for the fax relay. This TLV can be set on-the-fly. If this port is not specified by the host during the call setup, per RFC 1889, by default the source RTCP port is at an offset of 1 from the source RTP port.

Used in:

0x1E Generic PPL ICB in:

*Resource Attribute Configure* message

*Route Control* message

*Outseize Control* message

| Byte | Description           |
|------|-----------------------|

| 4, 5 | Value[0] RTCP Port |

### 0x01EA VoIP Terminal Capabilities

The *Resource Attribute Query* message is used to query an IP endpoint's terminal capabilities using this TLV. The report returned is based on the resource profile assigned to the module.

**Important!** The VoIP Terminal Capabilities can be queried by addressing either the IP Address AIB or Extended Span/Channel AIB embedded within the Address Element TLV.

Used in:

*Resource Attribute Query* message

| Byte | Description                                                                                                                                                      |

### 0x01EB RTP Timer Timeout (VDAC-ONE)

#### 0x01EB Initial Media Inactivity Timeout (IP Network Interface Series 2 Card)

Allows you to create a timer for monitoring the first incoming packet (for example, RTP, RTCP, or T.38) for each channel. If the timer expires before the first packet is received, a PPL Event Indication is generated, with an Event ID of 0x07.

Used in:

| 6, 7 | RTP Timer Timeout Value (2 Bytes - 10 ms increments)<br>0x0000 - 0xFFFF ms<br>0x0000 is the default, and it means that the timer is disabled.<br>Any other value automatically enables the timer to that value. |

**0x01EC Media Inactivity Detection Timer**

Use this TLV to create a timer for monitoring the incoming RTCP packets (VDAC-ONE) or UPD packets (IPN Series 2) at a per module or a per channel basis to detect possible media inactivity occurrence. When this timer is enabled for a particular channel, if the configured timer value has elapsed and no RTCP/UPD packets are received, then this timer will expire and generate a PPL Event Indication with Event ID of 0x08 to alert the host of a possible media inactivity detection. RTCP/UPD must be supported by remote endpoints for this TLV to work.

Used in:

0x1E Generic PPL ICB in:

*Resource Attribute Configure* message

*Route Control* message

*Outsize Control* message (not for SIP or H.323)

| Byte | Description                                                                                                                                                                                                  |

| 6, 7 | RTP Timer Timeout Value (2 Bytes - 10 ms increments)<br>0x00 - 0xFFFF ms.<br>0x00 is the default, and it means that the timer is disabled.<br>Any other value automatically enables the timer to that value. |

**0x01ED RFC 2833 Jitter Buffer Size**

Indicates the size of the RTP jitter buffer in milliseconds. The range is 0-400 milliseconds. The default is 200 milliseconds.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                                                                   |
|------|-----------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x01ED                                                                                    |
| 2, 3 | Length 0x0002                                                                                 |
| 4, 5 | Value[0] Value in milliseconds.<br>0x0000-0x0190 (0-400 ms)<br>0x00C8 (200 ms) is the default |

**0x01EE Invalid Packet Alarm Threshold**

Indicates the alarming threshold for the number of invalid non-RFC 2833 packets received by the CSP. The CSP generates an alarm every time the number of invalid packets exceeds the threshold limit in a one-second period. The alarming is on a per RFC 2833 channel basis.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x01EE                                                                                                      |
| 2, 3 | Length 0x0002                                                                                                   |
| 4, 5 | Value[0,1] Number of invalid packets that justify alarm generation.<br>0x0000 - 0xFFFF<br>0x0032 is the default |

**0x01EF Initial UDP Port Number**

Specifies the first UDP port number that will be used for receiving the RFC 2833 stream from an endpoint. The CSP increments the port number beyond this "seed" by two for every new call. The port number rolls over to the initial value once all the configured ports are exhausted.

You specify the number of UDP ports in the Number of UDP Ports 0x01F0.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                                                                              |
|------|----------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x01EF                                                                                               |
| 2, 3 | Length 0x0002                                                                                            |
| 4, 5 | Value[0,1] Initial port number above 1024.<br><br>0x0400 - 0x2710 (1024-10,000)<br>0x2710 is the default |

**0x01F0    Number of UDP Ports**

Specifies the total number of RFC 2833/RTP/UDP ports that the CSP is allowed to open. For a multiport scheme, this number is the number of RFC 2833 channels requested by a host application. Select 0 to specify that only one port needs to be opened that will multiplex all of the RFC 2833 streams. Any value other than 0 implies a multi-port scheme and the actual number of UDP ports required for each RFC 2833 channel basis.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                                                                                                                                                                                |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag      0x01F0                                                                                                                                                                                            |
| 2, 3 | Length    0x0002                                                                                                                                                                                           |
| 4, 5 | Value[0,1] 0 - implies single port scheme.<br>1 is the default<br><br>Any other value implies multiport scheme.<br><br>The number should be equal to or less than the<br>the CSP maximum channel capacity. |

**0x01F1 RFC 2833 Dynamic Payload Type**

Indicates the dynamic payload type number that the CSP will utilize for specifying the RFC 2833 multi-unicast media stream to the peer end-point.

Used in:

*VoIP Protocol Configure message*

*VoIP Protocol Query message*

*Outseize Control message*

*Route Control message*

*Resource Attribute Configure message*

| Byte | Description                                                                                                                                                                                                            |

| 0, 1 | Tag 0x01F1                                                                                                                                                                                                             |
| 2, 3 | Length 0x0001                                                                                                                                                                                                          |
| 4, 5 | Value[0,1] 0-127 Dynamic Payload Type (0x00 - 0x7F)<br><br>Default is 101 (0x65)<br><br>Cantata recommends that you use values 101-127 (0x60 - 0x7F).<br><br>Values 102, 103, and 105 are reserved. (0x66, 0x67, 0x69) |

**0x01F2 RFC 2198 Dynamic Payload Type**

Indicates the dynamic payload type number that the CSP will utilize for specifying the RFC 2198 redundant RTP payload to the peer end-point.

Used in:

*VoIP Protocol Configure* message

*Outsize Control* message

*Route Control* message

*Resource Attribute Configure* message

| Byte | Description                                                                                                                                                                                                                                                      |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x01F2                                                                                                                                                                                                                                                       |
| 2, 3 | Length 0x0001                                                                                                                                                                                                                                                    |
| 4, 5 | Value[0,1] 0-127 Dynamic Payload Type (0x00 - 0x7F)<br><br>Default is 104 (0x68)<br><br>Cantata recommends that you use values 96-127 (0x60 - 0x7F) for the IP Network Interface Series 2 Card.<br><br>Values 102, 103, and 105 are reserved. (0x66, 0x67, 0x69) |

#### **0x0262 Use SIP Local Port**

Use this TLV to specify the local SIP port number. The default port number is 0x13C4 (5060).

Used in:

*VoIP Protocol Configure* message

| Byte | Description            |
|------|------------------------|
| 0, 1 | Tag 0x0262             |
| 2, 3 | Length 0x0002          |
| 4, 5 | Value[0,1] Port Number |

#### **0x0263 Use SIP Remote Port/Default Proxy Port**

Use this TLV to specify the port number of a remote SIP server. The default port number is 0x13C4 (5060).

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                              |
|------|------------------------------------------|
| 0, 1 | Tag 0x0263                               |
| 2, 3 | Length 0x0002                            |
| 4, 5 | Value[0,1] Port Number<br>5060 (default) |

**0x0264 Use SIP Remote Host/Default Proxy Host**

Use this TLV to specify the remote default proxy host. The value is a null-terminated ASCII string representing either an IP address (for example, 10.10.10.10) or domain name (for example, sip.excel.com). To de-configure the SIP default proxy host use this value: 0.0.0.0.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                        |
|------|------------------------------------|
| 0, 1 | Tag 0x0264                         |
| 2, 3 | Length Variable                    |
| 4-N  | Value Null terminated ASCII string |

**0x0265 Use SIP Site ID**

Use this TLV to specify the site ID that is used to generate the call ID. The default value is UNSET.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte    | Description                                                                   |
|---------|-------------------------------------------------------------------------------|
| 0, 1    | Tag 0x0265                                                                    |
| 2, 3    | Length Variable                                                               |
| 4 . . . | Value[0 . . .] Site ID (Null terminated ASCII text string)<br>EXCEL (Default) |

**0x0266 Use SIP Anonymous Caller**

Use this TLV to specify the default caller number that is used when no caller number is specified. The default caller number is 0x0000000000000000 (00000000).

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte    | Description                                                      |
|---------|------------------------------------------------------------------|
| 0, 1    | Tag 0x0266                                                       |
| 2, 3    | Length Variable                                                  |
| 4 . . . | Value[0 . . .] Caller Number (Null terminated ASCII text string) |

**0x0267    Use SIP Invite T1 Timer**

Use this TLV to specify the T1 timer value for an INVITE request in milliseconds. The default value is 0x1F4 (500 milliseconds).

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                   |
|------|-------------------------------|
| 0, 1 | Tag      0x0267               |
| 2, 3 | Length    0x0004              |
| 4-7  | Value[0-3] T1 Timer (4 bytes) |

**0x0268    Use SIP BYE T1 Timer**

Use this TLV to specify the T1 timer value for BYE in milliseconds. The default value is 0x1F4 (500 milliseconds).

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                   |
|------|-------------------------------|
| 0, 1 | Tag      0x0268               |
| 2, 3 | Length    0x0004              |
| 4-7  | Value[0-3] T1 Timer (4 Bytes) |

**0x0269    Use SIP T2 Timer**

Use this TLV to specify the T2 timer value in milliseconds. The default value is 0xFA0 (4000 milliseconds).

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                   |
|------|-------------------------------|
| 0, 1 | Tag      0x0269               |
| 2, 3 | Length    0x0004              |
| 4-7  | Value[0-3] T2 Timer (4 Bytes) |

**0x026A Use SIP Maximum Retransmissions Invite**

Use this TLV to specify the maximum retransmissions for an INVITE request. The default value is 0x07.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                              |
|------|------------------------------------------|
| 0, 1 | Tag 0x026A                               |
| 2, 3 | Length 0x0001                            |
| 4    | Value[0] Maximum Number of Transmissions |

**0x026B Use SIP Max Retransmissions BYE**

Use this TLV to specify the maximum retransmissions for a BYE request (any request other than INVITE). The default value is 0x0B.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                    |
|------|--------------------------------|
| 0, 1 | Tag 0x026B                     |
| 2, 3 | Length 0x0001                  |
| 4    | Value[0] Maximum Transmissions |

**0x0270 SIP Tunnel Type**

For all outgoing messages, this TLV enables and disables the use of tunneled data and specifies the tunneled data type.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                                           |
|------|-----------------------------------------------------------------------|
| 0, 1 | Tag 0x0270                                                            |
| 2, 3 | Length 0x0002                                                         |
| 4, 5 | Value[0,1] 0x0001 No tunneling (Default)<br>0x0002 CSP UPDF Tunneling |

**0x0272 Use SIP Registration Timeout**

Use this TLV to specify the default registration expiration period in seconds that is used when no registration expiration period is specified. The default value is 0x00000E10 (3600 seconds).

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                         |
|------|-----------------------------------------------------|
| 0, 1 | Tag 0x0272                                          |
| 2, 3 | Length 0x0004                                       |
| 4-7  | Value[0-3] Registration Expiration Period (4 Bytes) |

**0x0274 Use No Local Media**

Use this TLV to specify the way to handle a situation where there is no VDAC-ONE or IP Network Interface Series 2 card.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                                                                                                                                                                                                  |

| 4,5  | Value[0,1] MSB - Major Version<br>LSB - Minor Version |

### 0x0279 SIP Local Route Lookup

Use this TLV to enable and disable local registration lookup, even if the Route Control message has the “To” IP address. If this TLV is enabled, the supplied “To” IP address is ignored. If you use internal routing and you want to make a SIP-to-SIP call, Cantata recommends enabling this TLV. You can enable and disable the local route lookup feature for an individual call by using the NPDI SIP Local Lookup TLV (0x2914).

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                    |
|------|------------------------------------------------|
| 0, 1 | Tag 0x0279                                     |

**0x027B Session Interval**

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

Use this TLV to set the value of the session-expire header (in seconds) in the SIP messages generated by the CSP.

| Byte | Description                                                    |
|------|----------------------------------------------------------------|
| 0, 1 | Tag 0x027B                                                     |
| 2, 3 | Length 0x0004                                                  |
| 4-7  | Value[0] Variable<br>1800 (30 minutes) (Default) 0x00 00 07 08 |

**0x027C Min-SE Interval**

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

Use this TLV to set the Min-SE header field (in seconds) which conveys the minimum allowed value for the session timer. The Min-SE Interval has to be less than the Session Interval. The maximum value is 0x7F FF FF FE.

| Byte | Description                                                  |

| 0, 1 | Tag 0x027C                                                   |
| 2, 3 | Length 0x0004                                                |
| 4-7  | Value[0] Variable<br>300 (5 minutes) (Default) 0x00 00 01 2C |

**0x027D SIP Transport Type**

Specifies the default transport type for outbound call. If this TLV does not appear in the VoIP Protocol Configure message, the CSP uses the default - UDP.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                   |
|------|-------------------------------|
| 0, 1 | Tag 0x027D                    |

| 4-7  | Value[0-3] 1 - UDP<br>2 - TCP |

**0x027F SIP Message Information Mask**

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

The host uses this TLV to specify the additional SIP message information to the host in the *Request for Service with Data* message.

| Byte | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 0x027E SIP Persistent Sockets

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

This TLV forces all TCP sockets to be persistent.

| Byte | Description                                        |
|------|----------------------------------------------------|
| 0, 1 | Tag 0x027E                                         |
| 2, 3 | Length 0x0001                                      |
| 4-7  | Value[0-3] 0     disable (default)<br>1     enable |

### 0x0280 SIP Existing Socket Reuse

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

For Connection oriented sockets, this TLV allows (or prevents) the reuse of any SIP socket which may exist between this host and the target endpoint. When this TLV is disabled, a new socket will be opened for each SIP Request.

| Byte | Description                                        |
|------|----------------------------------------------------|
| 0, 1 | Tag 0x0280                                         |
| 2, 3 | Length 0x0001                                      |
| 4-7  | Value[0-3] 0     disable (default)<br>1     enable |

### 0x0281 SIP Idle Socket Timeout

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

For connection oriented sockets that are not persistent, this TLV maintains an idle timer to determine when a socket should be closed.

| Byte | Description                                                                                                                                                                      |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x0281                                                                                                                                                                       |
| 2, 3 | Length 0x0002                                                                                                                                                                    |
| 4-7  | Value[0-3] The number of idle seconds to wait before<br>closing a non-persistent socket.<br><br>Default is 32 seconds.<br>Minimum is five seconds.<br>Maximum is 32,766 seconds. |

**0x0282 PPL Event Notification Mask**

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**0x0283 Minimum Registration Duration**

Used in:

*VoIP Protocol Configure* message

| Byte | Description                                |
|------|--------------------------------------------|
| 0, 1 | Tag 0x0283 - Minimum Registration Duration |
| 2,3  | Length 0x0004                              |
| 4-7  | Value[0-3] Time period in seconds          |

**0x0284 Resynchronize VoIP Media Parameter**

Use this TLV to resynchronize VoIP media parameters (maintained locally by SIP and H.323 software) after the *Resource Attribute Configure* message is sent to the CSP to change the underlying VoIP media resource configuration.

Used in:

*VoIP Protocol Configure* message

| Byte | Description                                      |
|------|--------------------------------------------------|
| 0, 1 | Tag 0x0284                                       |
| 2, 3 | Length 0x0001                                    |
| 4-7  | Value[0-3] 0 - No operation<br>1 - Resynchronize |

### 0x02BC Gatekeeper IP and Port

The Gatekeeper IP and Port Configure TLV is used only if the RAS module is configured during the stack configuration.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte   | Description                                                                                                                                            |

**0x02C1 Vendor ID**

Used for Gateway H.323 ID registration as well as Vendor ID. The value is a ASCII null terminated string that spells out the default value “EXCEL-CSP” as indicated below.

**Important!** You cannot deconfigure the Vendor ID.

Used in:

*0x0033 NPD Universal ICB in:*

*VoIP Protocol Configure message*

*VoIP Protocol Query message*

| Byte | Description           |
|------|-----------------------|
| 0, 1 | Tag 0x2C1 Vendor ID   |
| 2, 3 | Length 0x0A (Default) |
| 4    | Value[0] 0x45 E       |
| 5    | Value[1] 0x58 X       |
| 6    | Value[2] 0x43 C       |
| 7    | Value[3] 0x45 E       |
| 8    | Value[4] 0x4C L       |
| 9    | Value[5] 0x2D --      |

| 4, 5 | Value[0, 1] Auto Discovery<br>0x0000 Disabled (Default)<br>0x0001 Enabled |

### 0x02C3 Gatekeeper Auto Registration

Used in:

*VoIP Protocol Configure message*

*VoIP Protocol Query message*

| Byte | Description                                                                  |
|------|------------------------------------------------------------------------------|
| 0, 1 | Tag 0x2C3 Auto Registration                                                  |
| 2, 3 | Length 0x0002                                                                |
| 4, 5 | Value[0, 1] Auto Registration<br>0x0000 Disabled (Default)<br>0x0001 Enabled |

**0x02C4 Gateway E164**

This TLV contains the alias address which is added to the outbound H.323 setup message if the *Outseize Control* message or *Route Control* message does not contain the calling party number.

You can deconfigure the Gateway ID by setting this value to Null.

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

| Byte | Description                                                                 |
|------|-----------------------------------------------------------------------------|

**0x02D5 H.245 Tunneling Configure**

Used in:

*VoIP Protocol Configure* message

*VoIP Protocol Query* message

This TLV globally turn tunneling on and off. When this TLV is set to enable, the IP Signaling card accepts incoming H.323 calls with the H.245 tunneling feature.

| Byte | Description                                    |

| 4-7  | Value[0] 0 - Disabled (default)<br>1 - Enabled |

**0x05DC File Management Configuration**

Use this TLV to specify the type of server to be used for recorded voice files. This TLV is used in the *Generic Card Configure* message and in the response to the *Generic Card Query* message for the DSP Series 2 card.

| Byte | Description                              |
|------|------------------------------------------|
| 0, 1 | Tag 0x05DC File Management Configuration |
| 2, 3 | Length 0x0001                            |
| 4    | Value[0] 0x01 NFS                        |

**0x05DD Server Address**

Use this TLV to specify the name and location of the NFS server used for voice files. This TLV is used in the *Generic Card Configure* message and in the response to the *Generic Card Query* message.

| Byte      | Description                                                |
|-----------|------------------------------------------------------------|
| 0, 1      | Tag 0x05DD Server Address                                  |
| 2, 3      | Length Variable                                            |
| 4, 5      | Value[0] Server ID (application-defined)                   |
| 6-9       | Value[1] Primary IP Address (all zeros deletes the socket) |
| 10, 11    | Value[2] Server Name Length                                |
| 12-N      | Value[3] Server Name                                       |
| (2 bytes) | Value[4] Mount Name Length (max 32 bytes)                  |
| ...       | Value[5] Mount Name of Server                              |

**0x05DF Vocabulary Index File**

Use this TLV to specify the server ID, path, and name for the Vocabulary Index File, which in turn tracks the name, ID, and location of recorded voice files.

This TLV is used in the *Generic Card Configure* message and in the response to the *Generic Card Query* message.

| Byte      | Description                                                                                                                                                                                                                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1      | Tag 0x05DF Vocabulary Index File                                                                                                                                                                                                                                                                                        |
| 2, 3      | Length Variable                                                                                                                                                                                                                                                                                                         |
| 4, 5      | Value[0, 1] Primary Server ID (ID of server the file is on)                                                                                                                                                                                                                                                             |
| 6, 7      | Value[2, 3] Secondary Server ID (For TFTP only--future). This is a secondary Server to look for the Vocabulary Index File (VIF) on. Any time the VIF is updated, the software tries the primary server, and if there is no response, attaches to the secondary server. When the VIF is updated, all caches are cleared. |
| 8, 9      | Value[4, 5] Primary File Name Length                                                                                                                                                                                                                                                                                    |
| 10-N      | Value[6-N] Primary File Name with Path, not including Mount name (max 100 bytes). The path must begin with one forward slash ( / ) or two backward slashes ( \\ )                                                                                                                                                       |
| (2 bytes) | Secondary Name Length (0=no secondary file)                                                                                                                                                                                                                                                                             |
| (... -N)  | Secondary File Name with Path, not including Mount name (max 100 bytes). The path must begin with one forward slash ( / ) or two backward slashes ( \\ )                                                                                                                                                                |

**0x05E0 File ID**

Use this TLV to identify recorded voice files numerically.

This TLV is used in the *DSP Cache Modify*, *Play File Start*, and *Record File Start* messages.

| Byte | Description                                                                                                                                                                                                                                                                                                                 |

| 2, 3 | Length 0x0004                                                                                                                                                                                                                                                                                                               |
| 4-7  | Value[0] File ID<br><br><u>RAN IDs 0x00100000 or higher:</u><br>These must be played alone (not chained), and the CSP must first be configured for NFS with the <i>Generic Card Configure</i> message. Files with these IDs are not stored on the card.<br><br><u>RAN IDs lower than 0x00100000:</u><br>You can chain these |

**0x05E1 File Format**

Use this TLV to specify the file format and encoding format for recorded voice files for file IDs of 0x00100000 or higher in the *Play File Start* message and in the *Record File Start* message.

Also use this TLV in the *DSP Cache Modify* message when the Action field is set to Copy (the Encoding Format field is ignored; the encoding format of the file copy will always be the same format as the original file).

| Byte | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**0x05E2 File Location**

Use this TLV to specify the location of recorded voice files.

This TLV is mandatory for file IDs of 0x00100000 or higher in the *Play File Start* message, and in the *Record File Start* message.

It is also mandatory in the *DSP Cache Modify* message when the Action field is set to Copy.

| 4, 5 | Value[0, 1] Primary Server ID                                                                         |
| 6, 7 | Value[2, 3] Secondary Server ID                                                                       |
| 8-N  | Value[4-N] Filename, not including Mount name<br>(must begin with / or \\ )<br>128 characters maximum |

### 0x05E3 Gain

Use this TLV to modify the gain of recorded voice files.

This TLV is used in the following messages:

- *Play File Start*
- *Record File Start*
- *Play File Modify*
- *Record File Modify*

| Byte | Description                                                                                         |
|------|-----------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x05E3 Gain                                                                                     |
| 2, 3 | Length 0x0001                                                                                       |
| 4    | Value[0] Gain, expressed in decibels<br>Minimum -54 (0xCA)<br>Maximum 24 (0x18)<br>Default 0 (0x00) |

### 0x05E4 Speed

Use this TLV to modify the speed of recorded voice files.

This TLV is used for all file IDs in the *Play File Start* message and in the *Play File Modify* message when the Action field is set to Modify.

| Byte | Description                                                                                                                                                                            |

| 0, 1 | Tag 0x05E4 Speed                                                                                                                                                                       |
| 2, 3 | Length 0x0002                                                                                                                                                                          |
| 4, 5 | Value[0, 1] Speed, expressed in percent<br>Allowable values:<br>50 (%) (0x32)<br>75 (%) (0x4B)<br>100 (%) (0x64) Default Value<br>200 (%) (0xC8)<br>300 (%) (0x12C)<br>400 (%) (0x190) |

### 0x05E5 Barge In

Use this TLV in the *Play File Start* and *Resource Create* message to enable barge-in for recorded files or a conference broadcast.

| Byte | Description                                                                                                                                                                                      |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x05E5 Barge In                                                                                                                                                                             |
| 2, 3 | Length: 0x0001                                                                                                                                                                                   |
| 4    | Value[0]: Barge In Flag<br>Bit 0<br>0 = Barge In Disabled (default for Play files)<br>1 = Barge In Enabled (default for conferencing (broadcast))<br>Bit 1-7<br>Reserved (should be set to 0x00) |

**0x05E6 File Event Descriptor**

Use this TLV in the *Play File Start Record File Start* messages to configure the generation of Call Processing Events related to the playing and recording of files..

| Byte | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**0x05E7 Playback Repeat**

Use this TLV in the *Play File Start* message to specify the number of times to repeat playing a recorded voice file or list of files, as well as the interval between repetitions and the total time for playing the file.

| Byte | Description                                                                                            |
|------|--------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x05E7 Playback Repeat                                                                             |
| 2, 3 | Length 0x0006                                                                                          |
| 4, 5 | Value[0, 1]<br>Number of times to repeat playing the file or list of files.<br>0xFFFF = Repeat Forever |
| 6, 7 | Value[2, 3]<br>Interval between repetitions (100 ms steps)<br>0x05 (Default for 500 ms)                |
| 8, 9 | Value[4, 5]<br>Total time file is played (100 ms steps)<br>0x0000 = Disable timer (Default)            |

**0x05E8 Beep Tone Parameters**

Use this TLV in the *Record File Start* message to enable Beep Tone, as well as its frequency, duration, and amplitude.

| Byte | Description                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x05E8 Beep Tone Parameters                                                                                      |
| 2, 3 | Length 0x0005                                                                                                        |
| 4    | Value[0] Beep Enable Flag<br>0 Disable<br>1 Enable (Default)                                                         |
| 5, 6 | Value[1, 2] Beep Frequency (Hz)<br>Minimum 100 (0x0064)<br>Maximum 3000 (0x0BB8)<br>Default 1000 (0x03E8)            |
| 7    | Value[3] Beep Duration (10 ms steps)<br>Minimum 3 (0x03)<br>Maximum 200 (0xC8)<br>Default 20 (0x14)                  |
| 8    | Value[4] Beep Amplitude, in decibel milliwatts (dBm)<br>Minimum -54 (0xCA)<br>Maximum 3 (0x03)<br>Default -15 (0xF1) |

**0x05E9 Initial Silence Timer**

Use this TLV in the *Record File Start* message to set the Initial Silence Timer.

Recording does not begin until voice is detected. If the Initial Silence Timer expires before voice is detected, the recording attempt is aborted. For example, if the default setting of 2500 milliseconds is used, the recording attempt is aborted if no voice is detected in the first 2500 milliseconds.

| Byte | Description                                                                                                                                 |
|------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x05E9 Initial Silence Timer                                                                                                            |
| 2, 3 | Length 0x0002                                                                                                                               |
| 4, 5 | Value[0-1] Timer (10 ms increments)<br>Minimum 1 (0x0001)<br>Maximum 65534 (0xFFFF)<br>Disable timer 65535 (0xFFFF)<br>Default 250 (0x00FA) |

**0x05EA Final Silence Timer**

Use this TLV in the *Record File Start* message to specify how much silence it takes at the end of a voice recording to trigger the card to stop recording.

| Byte | Description                                                                                                                                 |
|------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x05EA Final Silence Timer                                                                                                              |
| 2, 3 | Length 0x0002                                                                                                                               |
| 4, 5 | Value[0-1] Timer (10 ms increments)<br>Minimum 1 (0x0001)<br>Maximum 65534 (0xFFFE)<br>Disable timer 65535 (0xFFFF)<br>Default 250 (0x00FA) |

**0x05EB Maximum Record Timer**

Use this TLV in the *Record File Start message* to set the maximum length of time allowed for recording a message.

| Byte | Description                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x05EB Maximum Record Timer                                                                                               |
| 2, 3 | Length 0x0002                                                                                                                 |

**0x05EF Alarm Threshold Configure**

Each DSP Series 2 main board can store up to three hours of files in a local cache. Each parameter has a threshold that generates an alarm. The M and N values provide a filter. M samples out of N must exceed the threshold for an alarm to occur. Files are stored in one-second blocks.

This TLV is used in the following messages:

- *Generic Card Configure*
- *Generic Card Query*
- *VoIP Protocol Configure*

- *VoIP Protocol Query*

| Byte | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### 0x05F0 DSP 2 Main Board Memory Alarm Threshold Configure

Use this TLV to set the threshold in percentage of total blocks used, on a per-card basis. If recorded voice files are accessed through a Network File Server, then this value represents only the Temporary Cache memory space. Files are stored in one-second blocks.

If recorded announcements are accessed through a Network File Server, then this represents only the Temporary Cache memory space.

For the DSP Series 2 card, this TLV is used in the *Generic Card Configure* message and in the response to the *Generic Card Query* message.

| Byte | Description                                                                                 |

### 0x05F1 DSP Temporary Memory Alarm Threshold Configure

Use this TLV in the *Generic Card Configure* message to set the threshold in percentage of total blocks, and to disable the alarm. This is set on a per-card basis, and the same threshold is used for all DSPs that are configured for File Playback/Record on that DSP Series 2 card. Files are stored in one-second blocks.

| Byte | Description                                                                                  |
|------|----------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x05F1- DSP Temporary Memory Alarm Threshold Configure                                  |

### 0x05F2 Play File Queue

Use this TLV in the *Play File Start* message (0x011B) to add a file to the Play File Queue. The TLV supports all file IDs, and it works with both the Channel AIB and the Conference AIB.

If File A is playing and hasn't completed before you send File B, File B interrupts File A. This TLV causes File B to wait in queue so that File A can finish.

| Byte | Description                                                 |

| 2, 3 | Length: 0x0002                                              |
| 4, 5 | Value[0,1]<br>0x0000 - Queue<br>0x0001 - Override (Default) |

### 0x05F3 Vocabulary Index Read Information

This TLV is sent in the response to the *Generic Card Query* message. It indicates the number of files in the Vocabulary Index File (VIF) and checks the integrity of the VIF through a checksum.

| Byte | Description                                     |
|------|-------------------------------------------------|
| 0, 1 | Tag: 0x05F3 - Vocabulary Index Read Information |
| 2, 3 | Length: 0x0008                                  |
| 4-7  | Value[0-3] - Number of files in the Index file  |
| 8-11 | Value[4-7] - Vocabulary Index File checksum     |

### 0x05F4 Statistics Update Timer

Use this TLV in the *Generic Card Configure* message to set how often system statistics are updated.

| Byte | Description                                                                                       |

| 2, 3 | Length: 0x0002                                                                                    |
| 4, 5 | Value[0, 1] - Timer Value<br>Minimum: 1 (0x0001)<br>Maximum: 168 (0x00A8)<br>Default: 24 (0x0018) |

**0x05F5 Fixed Memory Statistics**

This TLV is reported in the response to the *Statistics Query* message. It includes the total, average, and maximum blocks of fixed memory used on a specific DSP chip. A history of these statistics is not maintained.

| Byte   | Description                                                                              |

| 10-13  | Value[6-9]: Cache Misses                                                                  |
| 14-17  | Value[10-13]: Cache Hits                                                                  |
| 18, 19 | Value[14, 15]: Average Free Blocks                                                        |

**0x05F7 DSP Function Statistics**

This TLV is included in the response to the *Statistics Query* message. It reports average free channels, minimum free channels, and total requests for each function on a specific DSP chip on a DSP module. This data is repeated for the Txmt0, Rcv0, Txmt1, and Rcv1.

| Byte   | Description                                                                                                 |

**0x05FB Silence Threshold**

Use this TLV in the *Record File Start* to set the Silence Threshold. When the Beep Amplitude is reached, silence is no longer assumed.

| Byte | Description                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x05FB - Silence Threshold                                                                                         |
| 2, 3 | Length: 0x0001                                                                                                          |
| 4    | Value[0] Beep Amplitude, in decibel milliwatts (dBm)<br>Minimum: -54 (0xCA)<br>Maximum: 3 (0x03)<br>Default: -25 (0xE7) |

**0x05FC Temporary Record File Timer**

Use this TLV in the *Record File Start* message to set the maximum amount of time that an internal recording will stay in the cache before expiring. The timer runs on a per file basis.

| Byte | Description                                                                                                    |
|------|----------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x05FC - Temporary Record File Timer                                                                      |
| 2, 3 | Length: 0x0002                                                                                                 |
| 4, 5 | Value[0, 1]: Timer Value, in seconds<br>Minimum: 0 (0x0000)<br>Maximum: 65535 (0xFFFF)<br>Default: 30 (0x001E) |

**0x05FD CPU Statistics**

This TLV may be included in the response to the *Statistics Query* message.

| Byte  | Description                                           |
|-------|-------------------------------------------------------|
| 0, 1  | Tag: 0x05FD CPU Statistics                            |
| 2, 3  | Length: 0x0034                                        |
| 4     | Value[0]: DSP Module                                  |
| 5     | Value[1]: DSP Chip                                    |
| 6     | Value[2]: Percentage Idle                             |
| 7     | Value[3]: Percentage of time in the kernel task       |
| 8     | Value[4]: Percentage of time in servicing interrupts  |
| 9     | Value[5]: Percentage of time in the tnettask task     |
| 10    | Value[6]: Percentage of time in the tdspx task        |
| 11    | Value[7]: Percentage of time in the tdspr task        |
| 12    | Value[8]: Percentage of time in the tnet task         |
| 13    | Value[9]: Percentage of time in the trac task         |
| 14    | Value[10]: Percentage of time in the tvrap task       |
| 15    | Value[11]: Total percentage of time                   |
| 16-19 | Value[12-15]: Number of ticks idle                    |
| 20-23 | Value[16-19]: Number of ticks in the kernel task      |
| 24-27 | Value[20-23]: Number of ticks in servicing interrupts |
| 28-31 | Value[24-27]: Number of ticks in the tnettask task    |
| 32-35 | Value[28-31]: Number of ticks in the tdspx task       |
| 36-39 | Value[32-35]: Number of ticks in the tdspr task       |
| 40-43 | Value[36-39]: Number of ticks in the tnettask task    |
| 44-47 | Value[40-43]: Number of ticks in the trac task        |
| 48-51 | Value[44-47]: Number of ticks in the tvrap task       |
| 52-55 | Value[48-51]: Total ticks                             |

**0x05FE Resource Point Statistics**

This TLV may be returned in the response to the *Statistics Query* message. Note: TLV 0x05F9, query type 0404 is only valid while addressing the Matrix Controller card slot to query Resource Points. It does not work, if you address the DSP Series 2 card slot to query Resource Points.

| Byte  | Description                            |
|-------|----------------------------------------|
| 0, 1  | Tag: 0x05FE Resource Point Statistics  |
| 2, 3  | Length: 0x0010                         |
| 4-7   | Value[0-3]: Points Configured          |
| 8-11  | Value[4-7]: Points Available           |
| 12-15 | Value[8-11]: Minimum Points Available  |
| 16-19 | Value[12-15]: Average Points Available |

**0x05FF DSP Cache Modify Action**

Use this TLV in the *DSP Cache Modify* message.

| Byte | Description                                                                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x05FF DSP Cache Modify Action                                                                                                                                                                                         |
| 2, 3 | Length: 0x0002                                                                                                                                                                                                              |
| 4, 5 | Value[0, 1]: Action<br>0x0000 - Clear Specific Cache (also requires one or more File ID TLVs)<br>0x0001 - Clear All Caches<br>0x0002 - Copy Specific Cache (also requires the File ID, File Format, and File Location TLVs) |

**0x0600 NFS User Group ID**

Use this TLV in the *Generic Card Configure* message if you want to modify the default NFS User Group ID information. You should send this TLV at the same time you are configuring the card for NFS (along with the File Management Configure TLV).

| Byte     | Description                            |
|----------|----------------------------------------|
| 0, 1     | Tag: 0x0600 - NFS User Group ID        |
| 2, 3     | Length: Variable                       |
| 4, 5     | Value[0, 1]: User ID (Default is 2001) |
| 6, 7     | Value[2, 3]: Group ID (Default is 100) |
| 8, 9     | Value[4, 5]: Local Name Length         |

**0x0601 NFS Poll Retries**

Use this TLV in the *Generic Card Configure* message to set the number of polls the NFS server can miss before being marked out of service.

| Byte | Description                                     |
|------|-------------------------------------------------|
| 0, 1 | Tag: 0x0601 - NFS Poll Retries                  |
| 2, 3 | Length: 0x0004                                  |
| 4, 5 | Value[0, 1]: NFS Poll Retries: Default = 0x0001 |
| 6, 7 | Value[2, 3]: NFS Read Retries: Default = 0x0001 |

**0x0602 Resource Type**

Use this TLV to identify the resource type in the following messages:

*Resource Create* (0x0124)

*Resource Modify* (0x0125)

*Resource Delete* (0x0126)

*Resource Connect* (0x0127)

| Byte | Description                                                                                                                                                                                                                                                                                          |

**0x0603 Channel/DSP Pool**

Use this TLV in the *Resource Create* (0x0124) message to indicate the available DSP resources for a conference..

| Byte | Description                                                                                                                            |
|------|----------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x0603 - Channel/DSP Pool                                                                                                         |
| 2, 3 | Length: 0x0002                                                                                                                         |
| 4, 5 | Value[0, 1]: Conference Location<br>0x0000 - Local DSP/Local Channel<br>0x0001 - Local DSP/Any Channel<br>0x0002 - Any DSP/Any Channel |

**0x0604 DTMF Clamping/Filtering Enable**

Use this TLV to enable DTMF Clamping/Filtering for a file or a conference.

*Play File Start* (0x011B) (when starting a file)

*Record File Start* (0x011E) (when starting a recording)

*Play File Modify* (0x011C) (play file in progress)

*Record File Modify* (0x011F) (record file in progress)

*Resource Create* (0x0124) (when creating a conference)

*Resource Modify* (0x0125) (existing conference /or when modifying channel parameters connected to conference or child conference)

*Resource Connect* (0x0127) (when connecting channels to conference/moving channels from parent to child conference)

| Byte | Description                                                                        |
|------|------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x0604 - DTMF Clamping/Filtering Enable                                       |
| 2, 3 | Length: 0x0002                                                                     |
| 4, 5 | Value[0, 1]: DTMF Clamping Mode<br>0x0000 - Disabled (Default)<br>0x0001 - Enabled |

**0x0605 EXS Conferencing Encoding Type**

Use this TLV in the *Resource Create* (0x0124) message to specify the encoding type for a conference over the EXNET ring.

| Byte | Description                                                                      |
|------|----------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x0605 - EXS Conferencing Encoding Type                                     |
| 2, 3 | Length: 0x0002                                                                   |
| 4, 5 | Value[0, 1]: Encoding Type<br>0x0000 - u-law<br>0x0001 - A-law<br>0x0002 - Mixed |

**0x0606    Monitor Conference Enable**

Use this TLV in the *Resource Create* (0x0124) message to create a Monitor Conference.

| Byte | Description                                                                                     |
|------|-------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x0606 - Monitor Conference Enable                                                         |
| 2, 3 | Length: 0x0002                                                                                  |
| 4, 5 | Value[0, 1]: Encoding Type<br>0x0000 - Disabled (Default)<br>0x0001 - Enable Monitor Conference |

**0x0607    Output Gain Control**

Use this TLV to set the output gain, in decibels, for a conference.

It is used in the in the following messages

*Resource Create* (0x0124)

*Resource Modify* (0x0125)

*Resource Connect* (0x0127) .

| Byte | Description                                                                                                  |
|------|--------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x0607 - Output Gain Control                                                                            |
| 2, 3 | Length: 0x0002                                                                                               |
| 4, 5 | Value[0, 1]: Output Gain (1 db steps)<br>Minimum: -40 (0xFFD8)<br>Maximum: 0 (0x0000)<br>Default: 0 (0x0000) |

**0x0608    Noise Gating Enable**

Use this TLV to enable and disable noise gating in a conference.

It is used in the following messages:

*Resource Create* (0x0124)

*Resource Modify* (0x0125)

*Resource Connect* (0x0127)

| Byte | Description                                                                  |
|------|------------------------------------------------------------------------------|
| 0, 1 | Tag:0x0608 Noise Gate Enable                                                 |
| 2, 3 | Length: 0x0002                                                               |
| 4, 5 | Value[0, 1]: Noise Gating<br>0x0000 - Disabled (Default)<br>0x0001 - Enabled |

**0x0609 Noise Gate Parameters**

Use this TLV in the *Resource Create* (0x0124) message to set parameters for gating noise, including:

- the time constant over which the noise level is checked
- the allowable noise level
- noise gating sensitivity

If noise gating sensitivity is set too low for a conference, there is a risk of clipped speech; if it is set too high, there is a risk of noise bleeding through.

| Byte | Description                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x0609 - Noise Gate Parameters                                                                               |
| 2, 3 | Length: 0x0006                                                                                                    |
| 4, 5 | Value[0, 1]: Time Constant (5 ms steps)<br>Min: 10 (0x000A)<br>Max: 100 (0x0064)<br>Default: 35 (0x0023)          |
| 6, 7 | Value[2, 3]: Maximum Noise Level (1 dBm steps)<br>Min: -54 (0xFFCA)<br>Max: -10 (0xFFFF)<br>Default: -20 (0xFFEC) |
| 8, 9 | Value[4, 5]: Noise Gating Sensitivity<br>0x0001 - Low<br>0x0002<br>0x0003- Default<br>0x0004<br>0x0005 - High     |

**0x060A Echo Suppression Enable**

Use this TLV to enable and disable echo suppression in a conference.

It is used in the following messages

*Resource Create* (0x0124)

*Resource Modify* (0x0125)

*Resource Connect* (0x0127)

| Byte | Description                                                                     |
|------|---------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x060A Echo Suppression Enable                                             |
| 2, 3 | Length: 0x0002                                                                  |
| 4, 5 | Value[0, 1]: Echo Suppression<br>0x0000 - Disabled (Default)<br>0x0001 - Enable |

**0x060B Echo Suppression Parameters**

Use this TLV in the *Resource Create* (0x0124) message to set decibel parameters for suppressing echo in conferences. The higher quality the network, the lower you can set these parameters.

| Byte | Description                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x060B Echo Suppression Parameters                                                                     |
| 2, 3 | Length: 0x0002                                                                                              |
| 4, 5 | Value[0, 1]: Echo Return Loss (1 db steps)<br>Min: -54 (0xFFCA)<br>Max: -6 (0xFFFA)<br>Default: -10 (0xFF6) |

**0x060C Automatic Gain Control Enable**

Use this TLV to enable and disable Automatic Gain Control.

It is used in the following messages

*Resource Create* (0x0124)

*Resource Modify* (0x0125)

*Resource Connect* (0x0127)

| Byte | Description                                                                          |
|------|--------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x060C Automatic Gain Control Enable                                            |
| 2, 3 | Length: 0x0002                                                                       |
| 4, 5 | Value[0, 1]: Automatic Gain Control<br>0x0000 - Disable (Default)<br>0x0001 - Enable |

**0x060D Automatic Gain Control Input Level**

Use this TLV in the *Resource Create* message (0x0124) to set the target input level in conferences.

| Byte | Description                                                                                              |
|------|----------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x060D Automatic Gain Control Input Level                                                           |
| 2, 3 | Length: 0x0002                                                                                           |
| 4, 5 | Value[0, 1]: Input Level (1 dBm steps)<br>Min: -54 (0xFFCA)<br>Max: -3 (0xFFFD)<br>Default: -22 (0xFFEA) |

**0x060E Automatic Gain Control Parameters**

Use this TLV in the *Resource Create* message (0x0124) to set the time constant over which gain is measured in a conference.

| Byte | Description                                                                                                   |
|------|---------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x060E Automatic Gain Control Parameters                                                                 |
| 2, 3 | Length: 0x0002                                                                                                |
| 4, 5 | Value[0, 1]: Time Constant (5 ms steps)<br>Min: 100 (0x0064)<br>Max: 20000 (0x4E20)<br>Default: 2000 (0x07D0) |

**0x060F Conference Failure Behavior**

Use this TLV in the *Resource Connect* message (0x0127) to choose whether a channel is purged or parked when a conference fails.

| Byte | Description                                                                                           |
|------|-------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x060F Conference Failure Behavior                                                               |
| 2, 3 | Length: 0x0002                                                                                        |
| 4, 5 | Value[0, 1]: Conference Failure Behavior<br>0x0000 - Purge Channel (Default)<br>0x0001 - Park Channel |

**0x0610 Conference ID**

This TLV is included in the response to the *Resource Create* message (0x0124) to identify a conference.

| Byte | Description                                                                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x0610 Conference ID                                                                                                                                             |
| 2, 3 | Length: 0x0004                                                                                                                                                        |

| 2, 3 | Length: 0x0002                                                                 |
| 4, 5 | Value[0, 1]: Forced Flag<br>0x0000 - Graceful Delete<br>0x0001 - Forced Delete |

**0x0612 Connection Type**

Use this TLV in the *Connect with Data* (0x0005) message to set up a one-way connection that is maintained during a matrix switchover. Do not use in the *Connect* (0x0000) message.

Use this TLV in the *Resource Connect* (0x0127) message to specify the connection type for a conferee.

Used in:

0x1E Generic PPL ICB in:

*Connect with Data* message

*Resource Connect* message

| Byte | Description                                                                                |
|------|--------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x0612 Connection Type                                                                |
| 2, 3 | Length: 0x0002                                                                             |
| 4, 5 | Value[0, 1]: Connection Type<br>0x0000 - 2-Way Connect (Default)<br>0x0001 - 1-Way Connect |

**0x0613 Conference Size**

Use this TLV in the *Resource Create* (0x0124) message to specify the size of the conference.

| Byte | Description                                   |
|------|-----------------------------------------------|
| 0, 1 | Tag: 0x0613 Conference Size                   |
| 2, 3 | Length: 0x0002                                |
| 4, 5 | Value[0, 1]: Conference Size<br>0x0002-0x0080 |

**0x0614 Offset and Length**

Use this TLV in the *Play File Start* message (0x011B) to begin playing a file at an offset from the beginning of the file, and to specify how long into the file to play so it doesn't have to play to the end.

Because the Offset and Length are in bytes, and because they represent bytes in a file, the application is responsible for managing the different encoding formats, and for how bytes should represent time.

You can use this TLV when queueing files, but you cannot use it when chaining files within a single message.

| Byte | Description                                           |
|------|-------------------------------------------------------|
| 0, 1 | Tag: 0x0614 Offset and Length                         |
| 2, 3 | Length: 0x0008                                        |
| 4-7  | Value[0-3]: Offset (bytes from the start of the file) |
| 8-11 | Value[4-7]: Length (bytes from the offset to play)    |

**0x0615 Append or Replace**

Use this TLV in the *Record File Start* message (0x011E) to specify whether to append to a file or to completely replace the file.

You can set the "File Not Found" behavior so that if you attempt to append to a file that is not found, you can create a new file or fail the open command.

The Append or Replace TLV is ignored for temporary records, which are always replaced. It is also ignored when copying a temporary record to a file.

| Byte | Description                                                                     |

| 4    | Value [0]<br>0x00 - Continuous Recording (default)<br>Recording controlled with <i>Record File Start</i> and <i>Record File Stop</i> messages<br><br>0x01 - Recording with PVD<br>RTP packets will only be sent during the time that Positive Voice is detected.<br>Use in conjunction with:<br>0x0689 - Start/Stop Sending RTP Packets<br>0x068A - Calendar Time Offset for Sending RTP Packets |

**0x0689 - Start/Stop Sending RTP Packets**

Use this TLV in the *Record File Modify* message to start or stop the sending of RTP packets with Positive Voice Detection.

To use this TLV, you must have previously sent a *Record File Start* message with the 0x0688 - RTP Record Mode TLV with the mode set to 0x01 - Recording with PVD.

| Byte | Description                                  |
|------|----------------------------------------------|
| 0, 1 | Tag: 0x0689 - Start/Stop Sending RTP Packets |
| 2, 3 | Length: 0x0001                               |
| 4    | 0x00 - Stop<br>0x01 - Start                  |

**0x068A - Calendar Time Offset for Sending RTP Packets**

Use this TLV in the *Record File Modify* message to indicate the time at which positive voice is detected. The host will be notified with a Call Processing Event message.

To use this TLV, you must have previously sent a *Record File Start* message with the 0x0688 - RTP Record Mode TLV with the mode set to 0x01 - Recording with PVD.

This TLV is used with the Start/Stop Sending RTP Packets TLV (0x0689) in the *Record File Modify* Message.

| Byte | Description                                                |
|------|------------------------------------------------------------|
| 0, 1 | Tag: 0x0689 - Calendar Time Offset for Sending RTP Packets |
| 2, 3 | Length: 0x0006                                             |
| 4-7  | Calendar Time Offset (seconds since Jan. 1, 1970)          |
| 8, 9 | Milliseconds                                               |

**0x068B Input Gain Control**

Use this TLV with the Channel AIB in the following messages to set the input gain, in decibels, for a conferee.

- *Resource Create* (0x0124)
- *Resource Modify* (0x0125)
- *Resource Connect* (0x0127)

| Byte | Description                                                                                   |
|------|-----------------------------------------------------------------------------------------------|
| 0, 1 | Tag: 0x068B Input Gain Control                                                                |
| 2, 3 | Length: 0x0002                                                                                |
| 4-5  | Input Gain (in 1 db increments)<br>Min -40 (0xFFD8)<br>Max +10 (0x000A)<br>Default 0 (0x0000) |

**0x068C FAX Page Range**

Use this TLV in the *Resource Connect* (0x0127) message to specify a page range for FAX transmission.

- To FAX a single page, enter same page number for Start Page and End Page.
- If the page range specified extends beyond the end of the TIFF file, the file will be transmitted to completion from the specified start page.
- If the specified start page is beyond the end of the TIFF file, then a Fax complete event shall be generated and no pages shall be transmitted.

| Byte | Description                       |
|------|-----------------------------------|
| 0, 1 | Tag: 0x068C FAX Page Range        |
| 2, 3 | Length: 0x0004                    |
| 4, 5 | Start Page<br>Default = 0x01      |
| 6, 7 | End Page<br>Default = End of File |

**0x068D Transit Connection Mode**

Use this TLV with the DSP Chip AIB in the following message to set the conference one-way (input only) temporarily, while the tone/file is being played.

- *Resource Create* (0x0124)
- *Resource Connect* (0x0127)

| Byte | Description                                                                                                                                 |

**0x09CA Add Global Title Group**

This TLV is used to add a new Global Title (GT) group. It automatically activates the newly configured entries. After that, all GT entries that were pending to be added are brought into service. All GT entries that were pending to be deleted are brought out of service and internal entry space becomes available for subsequent configurations. The index table is rebuilt automatically.

### 0x09CB Delete Global Title Group

When you delete a group, all Global Title (GT) entries belonging to this group are removed. This TLV automatically activates the newly configured entries. After that, all GT entries that were pending to be added in are brought into service. All GT entries that were pending to be deleted are brought out of service and internal entry space becomes available for subsequent configurations. The index table is rebuilt automatically.

### 0x09CC Add Global Title Entry

This TLV is used to add Global Title (GT) entries. It is not used for Global Title Translation (GTT) immediately. You can configure multiple GT entries before you activate them using the 0x09CE Build Index Table.

These newly configured GT entries are stored on the SS7 card but do not take effect until the SS7 card receives the Build Index command.

You can add 1,000 GT entries at a time up to a maximum of 100,000 for an SS7 card. If you configure GT entries after exceeding this maximum, you will receive the error code 0x552D. When the GT entry has been in the Active GT table you will receive the error code 0x5529. When the GT entry has been Standby GT table you will receive the error code 0x5528.

**0x09CD Delete Global Title Entry**

After the deleted Global Title (GT) Entry TLV is executed, the deleted GT Entry is not out of service immediately. It is used to do GTT until the index table is built which remove these GT entries from the GT table.

**0x09CE Build Index Table**

This TLV is used to activate configured GT entries. After the index table is built, all new added GT entries are in service and all deleted GT entries are out-of-service.

This TLV automatically activates the newly configured entries. After that, all GT entries that were pending to be added are brought into service. All GT entries that were pending to be deleted are brought out of service and internal entry space becomes available for subsequent configuration.

### **0x2716 Call Identity (Interworking Only)**

Used in:

NPDI Universal ICB (0x0033)

| Byte | Description                            |
|------|----------------------------------------|
| 0, 1 | Tag 0x2716                             |
| 2, 3 | Length Variable                        |
| 4-6  | Value[0] SS7 Point Code                |
| 7,8  | Value[1] Number of Call Identity Bytes |
| 9    | Value[2] Call Identity                 |

### **0x2717 Called Party Number**

Use this TLV to specify the called party number. This TLV and be used in Interworking and Standard environments.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

*Route Control* message

| Byte | Description                                                     |
|------|-----------------------------------------------------------------|
| 0, 1 | Tag 0x2717                                                      |
| 2, 3 | Length Variable                                                 |

| 5    | Value[1] Numbering Plan Identifier and Reverse Charge Indicator |
| 6    | Value[2] Number of Digits (N)                                   |
| 7    | Value[3] BCD Digit Pair 1                                       |
| :    | Value[4] BCD Digit Pair 2                                       |
| :    | Value[N]:                                                       |

### **0x2718 Calling Party Number (Connected Number)**

Use this TLV to specify the calling party number. This TLV can be used in both Interworking and Standard environments.

The Screening and Presentation Indication byte and Numbering Plan Identifier byte are SS7 Called Party Number and Calling Party Number parameters defined in ANSI T1.113 and ITU Q.763.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

*Route Control* message

| Byte | Description                                    |

| 0, 1 | Tag 0x272B                                                     |
| 2, 3 | Length Variable                                                |
| 4    | Value[0] Hop Counter<br>Bits 1-5 Hop Counter<br>Bits 6-8 Spare |

### 0x2737 Original Called Number (Interworking Only)

Used in:

0x0033 NPDI Universal ICB

| Byte | Description                                    |
|------|------------------------------------------------|
| 0, 1 | Tag 0x2737                                     |
| 2, 3 | Length Variable                                |
| 4    | Value[0] Type of Number                        |
| 6    | Value[1] Screening and Presentation Indicators |
| 7    | Value[2] Numbering plan indicator              |
| 8    | Value[3] Calling Party Category                |
| 9    | Value[4] Number of digits                      |
| 10   | Value[5] BCD digit pair 1                      |
| 11   | Value[6] BCD digit pair 2                      |
| :    | :                                              |

### 0x273C Redirecting Number (Interworking Only)

Used in:

0x0033 NPDI Universal ICB

| Byte | Description                                          |
|------|------------------------------------------------------|
| 0, 1 | Tag 0x273C                                           |
| 2, 3 | Length Variable                                      |
| 4    | Value[0] Type of Number                              |
| 5    | Value[1] Redirection Reason                          |
| 6    | Value[2] Screening and Presentation Indicators       |
| 7    | Value[3] Reverse charge and numbering plan indicator |
| 8    | Value[4] Category                                    |
| 9    | Value[5] Number of digits                            |
| 10   | Value[5] BCD digit pair 1                            |
| 11   | Value[6] BCD digit pair 2                            |
| :    | :                                                    |

### 0x273D Redirection Information (Interworking Only)

Used in:

0x0033 NPDI Universal ICB

| Byte | Description                                                  |
|------|--------------------------------------------------------------|
| 0, 1 | Tag 0x273D                                                   |
| 2, 3 | Length Variable                                              |
| 4    | Value[0] Type of Number                                      |
| 5    | Value[1] Redirecting indicator / original redirection reason |
| 6    | Value[2] Redirection counter / redirection reason            |

### 0x273E Redirection Number (Interworking Only)

Used in:

0x0033 NPDI Universal ICB

| Byte | Description                                                  |
|------|--------------------------------------------------------------|
| 0, 1 | Tag 0x273E                                                   |
| 2, 3 | Length Variable                                              |
| 4    | Value[0] Type of Number                                      |
| 5    | Value[1] Redirection indicator / original redirection reason |
| 6    | Value[2] Redirection counter / redirection reason            |

**0x2745 Transit Network Selection  
(Interworking Only)**

Used in:

0x0033 NPDI Universal ICB

**0x274E NPDI Message Type**

Use this TLV in the NPDI Universal ICB (0x0033) to indicate the message type. Most protocols require that you use the Message Type as the first TLV in the ICB. This TLV can be used in Interworking and Standard environments.

Used in:

NPDI Universal ICB (0x0033)

*Request for Service with Data message, Route Control message*

*Outseize Control message, Channel Released with Data message*

### 0x2752 Low Layer Compatibility (Interworking Only)

Used in:

0x0033 NPDI Universal ICB

| Byte | Description                                         |
|------|-----------------------------------------------------|
| 0, 1 | Tag 0x2752                                          |
| 2, 3 | Length Variable                                     |
| 4, 5 | Value[1] First byte of Q931 Low Layer Compatibility |

**0x2753    Calling Party Sub Address  
(Interworking Only)**

Used in:

0x0033 NPDI Universal ICB

| Byte | Description                                                                                      |
|------|--------------------------------------------------------------------------------------------------|
| 0, 1 | Tag    0x2753                                                                                    |
| 2, 3 | Length   Variable                                                                                |
| 4    | Value[1] Starts from the octet 2 of the calling party sub address of <i>ITU RECMN*Q.931 93</i> . |

**0x2754    Called Party Sub Address  
(Interworking Only)**

Used in:

0x0033 NPDI Universal ICB

| Byte | Description                                                                                      |
|------|--------------------------------------------------------------------------------------------------|
| 0, 1 | Tag    0x2754                                                                                    |
| 2, 3 | Length   Variable                                                                                |
| 4, 5 | Value[1] Starts from the octet 2 of the calling party sub address of <i>ITU RECMN*Q.931 93</i> . |

**0x2755    Low Layer Compatibility Layer 1 Info  
(Interworking Only)**

Used in:

0x0033 NPDI Universal ICB

| Byte | Description       |
|------|-------------------|
| 0, 1 | Tag    0x2755     |
| 2, 3 | Length   Variable |

|      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### **0x275A Generic Command (Interworking Only)**

Use this TLV to send a generic command to the network entity to perform some predefined command codes.

Used in:

0x0033 NPDI Universal ICB

| Byte | Description                               |
|------|-------------------------------------------|
| 0, 1 | Tag 0x275A                                |
| 2, 3 | Length Variable                           |
| 4, 5 | Value[0,1]Generic Command Length MSB, LSB |
| 6, 7 | Value[2,3] Generic Command MSB, LSB       |
| :    | :                                         |
| :    | Value[n] Generic Command MSB, LSB         |

### 0x275B Generic Command Response (Interworking Only)

Use this TLV to respond to generic command. The response code should be same as the command code to confirm the command (though not required).

Used in:

0x0033 NPDI Universal ICB

| Byte | Description                                        |
|------|----------------------------------------------------|
| 0, 1 | Tag 0x275B                                         |

### 0x2792    Source IP Address

Used in:

0x0033 NPD I Universal ICB in:

*Route Control* message

*Outseize Control* message

| Byte | Description                             |
|------|-----------------------------------------|
| 0, 1 | Tag            0x2792 Source IP Address |
| 2, 3 | Length        0x0004                    |
| 4-7  | Value[0-3]    IP Address                |

### 0x2793    Source RTP Port

Used in:

0x0033 NPD I Universal ICB in:

*Route Control* message

*Outseize Control* message

| Byte | Description                             |
|------|-----------------------------------------|
| 0, 1 | Tag            0x2793    Source IP Port |
| 2, 3 | Length        0x0004                    |
| 4, 5 | Value[0, 1]    0x0000                   |
| 6, 7 | Value[2, 3]    RTP Port                 |

**0x2794 Destination IP Address**

Used in:

NPDI Universal ICB (0x0033) in:

*Route Control* message

*Request for Service with Data* message

*Outseize Control* message

| Byte | Description                       |
|------|-----------------------------------|
| 0, 1 | Tag 0x2794 Destination IP Address |
| 2, 3 | Length 0x0004                     |
| 4-7  | Value[0-3] IP Address             |

**0x2795 Destination RTP Port**

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

*Route Control* message

*Outseize Control* message

| Byte | Description                     |
|------|---------------------------------|
| 0, 1 | Tag 0x2795 Destination RTP Port |
| 2, 3 | Length 0x0004                   |
| 4, 5 | Value[0, 1] 0x0000              |
| 6, 7 | Value[2, 3] RTP Port            |

**0x27B0 RTP Payload Type**

Use this TLV in the NPDI Universal ICB (0x0033) to configure the RTP Payload Type.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

*Route Control* message

*Outseize Control* message

**Important!** Do not confuse this TLV with 0x0100, which is the regular resource attribute TLV for RTP Payload Type. TLV 0x27B0 is the RTP Payload Type in NPDI format.

| * VDAC-ONE card only                                                                                 |                                                        |                            |

**0x27B1 RTP Payload Size**

Use this TLV in the NPDI Universal ICB (0x0033) to configure the RTP Payload Size.

By changing the multiple of the payload size, you can configure how much encoded PCM data a packet contains.

**Example:** For G.711 on the VDAC-ONE card, a 160-byte payload of encoded PCM data is sent at the G.711 Basic Packet Rate of every 20 milliseconds. But if you change the multiple for G.711 to 2x, then a 320-byte payload is sent every 40 milliseconds.

In effect, changing the multiple also changes the throughput available over an Ethernet network. Larger packets create greater network delay overall, but they use the Ethernet bandwidth more efficiently. Smaller packets may use the Ethernet bandwidth less efficiently, but they may provide better voice quality.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

*Route Control* message

*Outseize Control* message

**Important!** Do not confuse this TLV with 0x0101 which is the regular resource attribute TLV for RTP Payload Size. Tag 0x27B1 is the RTP Payload Size in NPDI format.

| Byte | Description                                                   |
|------|---------------------------------------------------------------|
| 0, 1 | Tag: RTP Payload Size (0x27B1)                                |
| 2, 3 | Length: 0x0002                                                |
| 4    | Value [0] Direction<br>0x00 Ingress<br>0x01 Egress            |
| 5    | Value [1]: Multiple of the Basic Packet Rate (Default = 0x01) |

**0x27B2 NPDI RTP Silence Suppression**

The RTP Silence Suppression TLV block enables and disables silence suppression.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

*Outseize Control* message

Do not confuse this TLV with Tag 0x0102 which is the regular resource attribute TLV for Silence Suppression. Tag 0x27B2 is the RTP Silence Suppression in NPDI format.

| Byte | Description                                            |
|------|--------------------------------------------------------|
| 0, 1 | Tag        NPDI RTP Silence Suppression (0x27B2)       |
| 2, 3 | Length     0x0001                                      |
| 4    | Value[0]   0x00    Disable (Default)<br>0x01    Enable |

### 0x27B3    NPDI RTP Connection Mode

This TLV block allows you to set the connection mode. A line can be connected to receive only, transmit only, or both.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

*Outseize Control* message

Do not confuse this TLV with TLV 0x01DB, which is the regular resource attribute TLV for RTP Connection Mode. Tag 0x27B3 is the RTP Connection Mode in NPDI format.

**0x27E4 H.245 Outbound Tunneling**

Used in:

*Route Control* message

*Outsize Control* message

You can send this TLV in the messages above for each H.323 outbound call initialization (on a per call basis) to configure H.245 tunneling for outbound calls.

This TLV has no effect unless the H.225 Tunneling Configure TLV (0x02D5) is enabled for inbound calls. The IP Signaling card can only use H.245 tunneling if inbound tunneling is enabled.

**0x290E NPD I SIP Proxy IP Address**

Use this TLV to specify the IP address of the SIP proxy server to which the request is sent. In an outbound call, this TLV specifies where the SIP Messages are sent. The information goes in the request URI of the SIP message.

Used in:

0x0033 NPD I Universal ICB in:

*Route Control* message

### 0x2910 NPDI SIP Route Type

Use this TLV to specify whether or not a SIP message should be sent to the default proxy. The TLV is used only when the host does not specify the proxy address in the *Route Control* message and the default proxy is desired for a particular call. Absence of this TLV implies that the destination can be reached directly.

| 4, 5 | Value SIP Response Code (2 Bytes)<br><br>This TLV, when reported in the PPL Event Indication for Event (0x0027/0x0028), will have any valid SIP Response value. The response code to be interpreted for event 0x0027 is as follows:<br>202 - Accepted (The REFER request is successful)<br>405 – Method Not Allowed (REFER request failed)<br>408 – Request Timed Out (REFER request failed)<br><br>The response code to be interpreted for event 0x0028 is as follows:<br>100 – Trying<br>200 - OK (The reference is successful)<br>503 - Service Unavailable (The reference failed)<br>603 - Decline (The reference failed) |

### 0x2916 SIP A Leg Transport Type

Reports to the host the default transport type of the A leg portion of the call.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

| Byte | Description          |
|------|----------------------|
| 0, 1 | Tag 0x2916           |
| 2, 3 | Length 0x0001        |
| :    | Value 1 UDP<br>2 TCP |

### 0x2917 SIP B Leg Transport Type

Reports or sets the default transport type on a per call basis. You set up the default value in the *VoIP Protocol Configure* message with the SIP Transport Type TLV.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

| Byte | Description          |
|------|----------------------|
| 0, 1 | Tag 0x2917           |
| 2, 3 | Length 0x0001        |
| :    | Value 1 UDP<br>2 TCP |

### 0x2919 NPDI SIP To Username

In a *Request for Service* message and PPL Event Indication, this TLV provides information parsed from the “To” header field of the incoming SIP message (for example INVITE or REGISTER). This TLV could be used in a *Route Control* message to specify the remote User Agent’s addressing information, which would be used to create the “To” header for the outgoing SIP message. Use this TLV to specify a username in the “To” header.

Used in:

0x0033 NPDI Universal ICB in:

*Outsize Control* message

*Request for Service with Data* message

*Route Control* message

| Byte | Description                          |
|------|--------------------------------------|
| 0, 1 | Tag 0x2919                           |
| 2, 3 | Length Variable                      |
| :    | Value A Null-terminated ASCII string |

### 0x291A NPDI SIP To Password

In a *Request for Service* message and PPL Event Indication, this TLV provides information parsed from the “To” header field of the incoming SIP message (for example INVITE or REGISTER). This TLV could be used in a *Route Control* message to specify the remote User Agent’s addressing information, which would be used to create the “To” header for the outgoing SIP message.

Use this TLV to specify a password in the “To” header.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

*Route Control* message

| Byte | Description                          |
|------|--------------------------------------|
| 0, 1 | Tag 0x291A                           |
| 2, 3 | Length Variable                      |
| :    | Value A Null-terminated ASCII string |

### 0x291B NPDI SIP To Host Name

In a *Request for Service* message and PPL Event Indication, this TLV provides information parsed from the “To” header field of the incoming SIP message (for example INVITE or REGISTER). This TLV could be used in a *Route Control* message to specify the remote User Agent’s addressing information, which would be used to create the “To” header for the outgoing SIP message.

Use this TLV to specify an IP address in the “To” header

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

*Route Control* message

| Byte | Description                          |
|------|--------------------------------------|
| 0, 1 | Tag 0x291B                           |
| 2, 3 | Length Variable                      |
| :    | Value A Null-terminated ASCII string |

### 0x291C NPDI SIP To Port

In a *Request for Service* message and PPL Event Indication, this TLV provides information parsed from the “To” header field of the incoming SIP message (for example INVITE or REGISTER). This TLV could be used in a *Route Control* message to specify the remote User Agent’s addressing information, which would be used to create the “To” header for the outgoing SIP message.

This TLV provides the port from the “To” address URL.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

*Route Control* message

| Byte | Description                                                                    |
|------|--------------------------------------------------------------------------------|
| 0, 1 | Tag 0x291C                                                                     |
| 2, 3 | Length 0x0004                                                                  |
| 4-7  | Value Variable<br>If this TLV is not present, a default value of 5060 is used. |

### 0x291E NPDI SIP Refer to Username

Use this TLV in a *PPL Event Request* message that is used to generate a REFER message. This TLV specifies the referred target User Agent’s addressing information which is used to create the Refer-To header for the outbound REFER request. Use this TLV to specify a username in the Refer-To header.

Used in:

0x0033 NPDI Universal ICB in:

*PPL Event Request* message

| Byte | Description                             |
|------|-----------------------------------------|
| 0, 1 | Tag 0x291E                              |
| 2, 3 | Length Variable                         |
| :    | Value[0] A NULL-terminated ASCII string |

#### **0x291F NPDI SIP Refer to Password**

Use this TLV in a *PPL Event Request* message that is used to generate a REFER message. This TLV specifies the referred target User Agent's addressing information which is used to create the Refer-To header for the outbound REFER request. Use this TLV to specify a password in the Refer-To header.

Used in:

0x0033 NPDI Universal ICB in:

*PPL Event Request* message

| Byte | Description                             |
|------|-----------------------------------------|
| 0, 1 | Tag 0x291F                              |
| 2, 3 | Length Variable                         |
| :    | Value[0] A NULL-terminated ASCII string |

#### **0x2920 NPDI SIP Refer to Host Name**

Use this TLV in a *PPL Event Request* message that is used to generate a REFER message. This TLV specifies the referred target User Agent's addressing information which is used to create the Refer-To header for the outbound REFER request. Use this TLV to specify a host IP address in the Refer-To header.

Used in:

0x0033 NPDI Universal ICB in:

*PPL Event Request* message

| Byte | Description                             |
|------|-----------------------------------------|
| 0, 1 | Tag 0x2920                              |
| 2, 3 | Length Variable                         |
| :    | Value[0] A NULL-terminated ASCII string |

**0x2921     NPDI SIP Refer to Port**

Use this TLV in a *PPL Event Request* message that is used to generate a REFER message. This TLV specifies the referred target User Agent's addressing information which is used to create the Refer-To header for the outbound REFER request. Use this TLV to specify the port in the Refer-To header.

Used in:

0x0033 NPDI Universal ICB in:

*PPL Event Request* message

| Byte | Description                                                    |
|------|----------------------------------------------------------------|
| 0, 1 | Tag     0x2921                                                 |
| 2, 3 | Length   0x0004                                                |
| :    | Value[0] If this TLV is not present, the default 5060 is used. |

**0x2923     NPDI SIP From User Name**

In a *Request for Service* message and PPL Event Indication, this TLV provides information parsed from the "From" header field of the incoming SIP message (for example INVITE or REGISTER). This TLV could be used in a *Route Control* message to specify the local User Agent's addressing information, which would be used to create the "From" header for the outgoing SIP message.

Use this TLV to specify a user name in the "From" header.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

*Route Control* message

| Byte | Description                              |
|------|------------------------------------------|
| 0, 1 | Tag     0x2923                           |
| 2, 3 | Length   Variable                        |
| :    | Value     A Null-terminated ASCII string |

**0x2924     NPDI SIP From Password**

In an *Request for Service* message and PPL Event Indication, this TLV provides information parsed from the "From" header field of the incoming SIP message (for example INVITE or REGISTER). This

TLV could be used in a *Route Control* message to specify the local User Agent's addressing information, which would be used to create the "From" header for the outgoing SIP message.

Use this TLV to specify a password in the "From" header.

Used in:

0x0033 NPD I Universal ICB in:

*Request for Service with Data* message

*Route Control* message

| Byte | Description                          |
|------|--------------------------------------|
| 0, 1 | Tag 0x2924                           |
| 2, 3 | Length Variable                      |
| :    | Value A Null-terminated ASCII string |

### 0x2925 NPD I SIP From Host Name

In an *Request for Service* message and PPL Event Indication, this TLV provides information parsed from the "From" header field of the incoming SIP message (for example INVITE or REGISTER). This TLV could be used in a *Route Control* message to specify the local User Agent's addressing information, which would be used to create the "From" header for the outgoing SIP message.

Use this TLV to specify an IP address in the "From" header.

Used in:

0x0033 NPD I Universal ICB in:

*Request for Service with Data* message

*Request for Service* message

| Byte | Description                          |
|------|--------------------------------------|
| 0, 1 | Tag 0x2925                           |
| 2, 3 | Length Variable                      |
| :    | Value A Null-terminated ASCII string |

### 0x2926 NPD I SIP From Port

In a *Request for Service* message and PPL Event Indication, this TLV provides information parsed from the "From" header field of the incoming SIP message (for example INVITE or REGISTER). This TLV could be used in a *Route Control* message to specify the local User Agent's addressing information, which would be used to create the "From" header for the outgoing SIP message.

This TLV provides the port from the “From” URL.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

*Request for Service with Data* message

| Byte | Description                                                                                                                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x2926                                                                                                                                                                                                                    |
| 2, 3 | Length 0x0004                                                                                                                                                                                                                 |
| 4-7  | Value Variable<br>If this TLV is not present, the configured local port is used in outbound calls (Route Control message) and port 5060 is used for incoming calls for registration (Request for Service and PPL Indication). |

### 0x2928 SIP From Display Name

This TLV contains the user name parsed from the display name in ASCII format.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

| Byte | Description                                                       |
|------|-------------------------------------------------------------------|
| 0, 1 | Tag 0x2928                                                        |
| 2, 3 | Length Variable (Maximum of 250 bytes)                            |
| 4-n  | Value A Null-terminated ASCII string containing From Display Name |

### 0x292D NPDI SIP Contact URI User Name

This TLV contains the user name parsed from the contact header in ASCII format.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

| Byte | Description                                                  |
|------|--------------------------------------------------------------|
| 0, 1 | Tag 0x292D                                                   |
| 2, 3 | Length Variable                                              |
| 4-n  | Value NULL Terminated ASCII string for SIP Contact user name |

**0x292E    NPDI SIP Contact Password**

This TLV contains the password in the contact header in ASCII format.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

| Byte | Description                                                   |
|------|---------------------------------------------------------------|
| 0, 1 | Tag      0x292E                                               |
| 2, 3 | Length   Variable                                             |
|      | Value    NULL Terminated ASCII value for SIP Contact password |

**0x292F    NPDI SIP Contact Hostname**

This TLV provides the IP address from the Contact URL in ASCII string.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

| Byte | Description                                                     |
|------|-----------------------------------------------------------------|
| 0, 1 | Tag      0x292F                                                 |
| 2, 3 | Length   Variable                                               |
|      | Value    NULL Terminated ASCII value for SIP 'Contact' hostname |

**0x2930    NPDI SIP Contact Port**

This TLV provides the port from Contact URL.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

| Byte | Description                                                                       |
|------|-----------------------------------------------------------------------------------|
| 0, 1 | Tag      0x2930                                                                   |
| 2, 3 | Length   0x0004                                                                   |
| 4-7  | Value    Variable<br>If this TLV is not present, a default value of 5060 is used. |

**0x2931    NPD SIP Contact Expires**

This TLV defines the seconds remaining before the Contact expires.

Used in:

0x0033 NPD Universal ICB in:

*Request for Service with Data* message

| Byte | Description          |
|------|----------------------|
| 0, 1 | Tag        0x2931    |
| 2, 3 | Length    0x0004     |
| 4-7  | Value [0-3] Variable |

**0x2933    SIP Contact Transport Type**

Specifies the transport type contained in the registration method.

Used in:

0x0033 NPD Universal ICB in:

*Setup Indication* message

*PPL Event Indication* message

| Byte | Description                    |
|------|--------------------------------|
| 0, 1 | Tag        0x2933              |
| 2, 3 | Length    0x0001               |
| 4-7  | Value[0]<br>1 - UDP<br>2 - TCP |

**0x2934    SIP Contact URI User Information Qualifier**

Use this TLV to append a user-defined ASCII string to the Contact URI user name in outbound SIP calls from the CSP. Specifically, the ASCII string is populated in the user information of the Contact-URI header in the outbound SIP INVITE message.

When the CSP is in a SIP/PSTN gateway environment, you can use this TLV to report the originating trunk group information in a PSTN-to-SIP call.

Used in:

0x0033 NPD Universal ICB in:

*Route Control* message

*Outseize Control* message

| Byte | Description                             |
|------|-----------------------------------------|
| 0, 1 | Tag 0x2934                              |
| 2, 3 | Length Variable                         |
| 4-n  | Value[0-n] Null-terminated ASCII string |

### 0x2935 SIP Contact URI Parameters

Use this TLV to receive and send Contact-URI parameters to and from host applications.

For inbound calls, this TLV carries all of the Contact URI parameters received by the SIP software in the *Request for Service with Data* message to host applications.

For outbound SIP calls, this TLV allows you to insert Contact URI parameters in SIP INVITE messages.

To report this TLV you must first set Bit 5 in the TLV *0x027F SIP Message Information Mask (4-79)*.

Used in:

0x0033 NPD Universal ICB in:

*Request for Service with Data* message

*Route Control* message

*Outseize Control* message

| Byte | Description                                                                    |
|------|--------------------------------------------------------------------------------|
| 0, 1 | Tag 0x2935                                                                     |
| 2, 3 | Length Variable                                                                |
| 4-n  | Value[0-n] Null-terminated ASCII string for URI parameters in the CONTACT-URI. |

### 0x2936 SIP Tunnel Type

For all outgoing messages, this TLV enables and disables the use of tunneled data and specifies the tunneled data type.

Used in:

0x0033 NPD I Universal ICB in:

*Route Control* message

| Byte | Description                                                           |
|------|-----------------------------------------------------------------------|
| 0, 1 | Tag 0x2936                                                            |
| 2, 3 | Length 0x0002                                                         |
| 4, 5 | Value[0-1] 0x0001 No tunneling (Default)<br>0x0002 CSP UPDF Tunneling |

### 0x2937 NPD I SIP Authenticate Scheme

Use this TLV to specify the authentication scheme: basic or digest (a scheme based on cryptographic hashes).

Used in:

0x0033 NPD I Universal ICB in:

*PPL Event Request* message with Event IDs 0x0C

| Byte | Description                          |
|------|--------------------------------------|
| 0, 1 | Tag 0x2937                           |
| 2, 3 | Length 0x0001                        |
| 4, 5 | Value[0-1] 0x00 Basic<br>0x01 Digest |

### 0x2938 NPD I SIP Authentication Realm

The TLV specifies the realm used in the www-authenticate header.

Used in:

0x0033 NPD I Universal ICB in:

*PPL Event Request* message with Event IDs 0x0C

| Byte | Description                                       |
|------|---------------------------------------------------|
| 0, 1 | Tag 0x2938                                        |
| 2, 3 | Length Variable                                   |
| 4-n  | Value[0-n] Null-terminated ASCII string for realm |

**0x2939 NPDI SIP Authenticate Username**

Use this TLV to specify the username used to authenticate the request.

Used in:

0x0033 NPDI Universal ICB in:

*PPL Event Request* message with Event IDs 0x0C

| Byte | Description                                          |
|------|------------------------------------------------------|
| 0, 1 | Tag 0x2939                                           |
| 2, 3 | Length Variable                                      |
| 4-n  | Value[0-n] NULL terminated ASCII string for username |

**0x293A NPDI SIP Authenticate Password**

Use this TLV to specify the password used to authenticate the request.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

*PPL Event Request* message with Event IDs 0x0C

| Byte | Description                                          |
|------|------------------------------------------------------|
| 0, 1 | Tag 0x293A                                           |
| 2, 3 | Length Variable                                      |
| 4-n  | Value[0-n] NULL Terminated ASCII string for password |

**0x293B NPDI SIP Authorization Username**

Use this TLV to specify the username used to generate the Authorization header for an outgoing request when the CSP receives a 401 response.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

| Byte | Description                                          |
|------|------------------------------------------------------|
| 0, 1 | Tag 0x293B                                           |
| 2, 3 | Length Variable                                      |
| 4-n  | Value[0-n] NULL Terminated ASCII string for username |

**0x293C NPDI SIP Authorization Password**

Use this TLV to specify the password used to generate the Authorization header for an outgoing request when the CSP receives a 401 response.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

| Byte | Description                                          |
|------|------------------------------------------------------|
| 0, 1 | Tag 0x293C                                           |
| 2, 3 | Length Variable                                      |
| 4-n  | Value[0-n] NULL Terminated ASCII string for password |

#### **0x293D NPDI SIP Proxy Authorization Username**

Use this TLV to specify the username used to generate Proxy-Authorization header for an outgoing request when the CSP receives a 407 response.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

| Byte | Description                                          |
|------|------------------------------------------------------|
| 0, 1 | Tag 0x293D                                           |
| 2, 3 | Length Variable                                      |
| 4-n  | Value[0-n] NULL Terminated ASCII string for username |

#### **0x293E NPDI SIP Proxy Authorization Password**

Use this TLV to specify the password used to generate the Proxy-Authorization header for an outgoing request when the CSP receives a 407 response.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

| Byte | Description                                         |
|------|-----------------------------------------------------|
| 0, 1 | Tag 0x293E                                          |
| 2, 3 | Length Variable                                     |
| 4-n  | Value[0-n] NULL Terminated ASCII value for password |

#### **0x293F NPDI SIP Authentication Timeout**

Use this TLV to specify the timeout for authentication response.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

*PPL Event Request* message with Event IDs 0x0C

| Byte | Description                                                                  |
|------|------------------------------------------------------------------------------|
| 0, 1 | Tag 0x293F                                                                   |
| 2, 3 | Length 0x01                                                                  |
| 4-n  | Value[0-n] Timeout in seconds<br>Minimum: 30 seconds<br>Maximum: 255 seconds |

### 0x2941 SIP Authorization Header

Use this TLV to specify the authorization header value in a SIP message.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

*Request for Service with Data* message

| Byte | Description                                                      |
|------|------------------------------------------------------------------|
| 0, 1 | Tag 0x2941                                                       |
| 2, 3 | Length Variable                                                  |
| 4-n  | Value[0-n] Null Terminated ASCII value for Authorization header. |

### 0x2942 SIP Proxy Authorization Header

Use this TLV to specify the SIP Proxy authorization header value in a SIP message.

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

*Request for Service with Data* message

| Byte | Description                                                            |
|------|------------------------------------------------------------------------|
| 0, 1 | Tag 0x2942                                                             |
| 2, 3 | Length Variable                                                        |
| 4-n  | Value[0-n] Null Terminated ASCII value for Proxy-Authorization header. |

**0x2943 SIP Authenticate Header**

Use this TLV to specify the WWW-Authenticate header value in a SIP message.

Used in:

0x0033 NPDI Universal ICB in:

*Release Channel with Data* message

| Byte | Description                                                          |
|------|----------------------------------------------------------------------|
| 0, 1 | Tag 0x2943                                                           |
| 2, 3 | Length Variable                                                      |
| 4-n  | Value[0-n] Null Terminated ASCII value for WWW-Authorization header. |

**0x2944 SIP Proxy-Authenticate Header**

Use this TLV to specify the Proxy-Authenticate header value in a SIP message.

Used in:

0x0033 NPDI Universal ICB in:

*Release Channel with Data* message

| Byte | Description                                                            |
|------|------------------------------------------------------------------------|
| 0, 1 | Tag 0x2944                                                             |
| 2, 3 | Length Variable                                                        |
| 4-n  | Value[0-n] Null Terminated ASCII value for Proxy-Authorization header. |

**0x294B Notify Status**

Used in:

0x0033 NPDI Universal ICB in:

| Byte | Description                                                                          |
|------|--------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x294B                                                                           |
| 2,3  | Length 0x0002                                                                        |
| 4, 5 | Value (0,1) Any appropriate SIP Response value.<br>(Typically 200 OK or 600 Decline) |

**0x294C Refer Spans Channel**

Used in:

0x0033 NPD Universal ICB in:

| Byte | Description             |
|------|-------------------------|
| 0, 1 | Tag 0x294C              |
| 2, 3 | Length 0x0003           |
| 4, 5 | Value(0,1) Span Number  |
| 6    | Value(2) Channel Number |

**0x294E SIP Remote IP Address**

This TLV reports the IP Address of the remote socket.

Used in:

0x0033 NPD Universal ICB in:

*Request for Service* message

| Byte | Description                                               |
|------|-----------------------------------------------------------|
| 0, 1 | Tag 0x294E                                                |
| 2, 3 | Length 0x0004                                             |
| 4-n  | Value[0-n] MSB of the IP Address<br>LSB of the IP Address |

**0x294F SIP Remote IP Port**

This TLV reports the IP Port of the remote socket.

Used in:

0x0033 NPD Universal ICB in:

*Request for Service* message

| Byte | Description                                         |
|------|-----------------------------------------------------|
| 0, 1 | Tag 0x294F                                          |
| 2, 3 | Length 0x0002                                       |
| 4-n  | Value[0-n] MSB of the IP Port<br>LSB of the IP Port |

**0x2950 SIP Call ID**

Use this TLV to specify the Call ID of the SIP message.

Used in:

*Route Control* message (ACK only)

*Outseize Control* message (ACK only)

*Request for Service with Data* message

| Byte | Description                                               |
|------|-----------------------------------------------------------|
| 0, 1 | Tag 0x2950                                                |
| 2, 3 | Length Variable                                           |
| 4-n  | Value[0-n] Null Terminated ASCII value of Call-ID header. |

**0x2951 SIP From Tag**

Use this TLV to specify the Tag value in the From Header of the SIP message.

Used in:

*Request for Service with Data* message

| Byte | Description                                               |
|------|-----------------------------------------------------------|
| 0, 1 | Tag 0x2951                                                |
| 2, 3 | Length Variable                                           |
| 4-n  | Value[0-n] Null Terminated ASCII value of Call-ID header. |

**0x2952 SIP to Tag**

Use this TLV to specify the Tag value in the To Header of the SIP message.

Used in:

*Request for Service with Data* message

| Byte | Description                                                |
|------|------------------------------------------------------------|
| 0, 1 | Tag 0x2952                                                 |
| 2, 3 | Length Variable                                            |
| 4-n  | Value[0-n] Null Terminated ASCII value of Tag in To header |

**0x2953 Subsequent Information Status**

If all the NPDI data cannot be sent from the CSP to the host in one *Request for Service (RFS) with Data* message, the remaining data is sent in the *PPL Event Indication* message (component ID 0x00A7 and event ID 0x23). If the CSP sends the data in multiple messages, the *RFS with Data* and subsequent PPL event indications, the CSP adds this TLV to those messages. This TLV indicates the sequence number of the message and whether there is more data to follow in the PPL Event Indication.

Similarly, if all the NPDI data cannot be sent from the host in the *Route Control* or *Outseize Control* message, the remaining data is sent in one or more *PPL Event Request* messages. Each of these messages has to include the proper sequence number.

Used in:

*Outseize Control* message

*Route Control* message

*PPL Event Request* message

*Request for Service with Data* message

*PPL Event Indications* message

| Byte | Description                                                                                                                                                                                                                                                                                                                                                                                                            |

**0x2954 SIP Request URI User Name**

Used to specify the user name in the Request URI. If the host provides the Request URI parameters, it must also provide the “To Header” parameters (see TLVs 0x2919, 0x291A, 0x291B, 0x291C). The host must also provide the URI host name and port name (See TLVs 0x2955 and 0x2956).

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

*Request for Service with Data* message

| Byte | Description                                                    |
|------|----------------------------------------------------------------|
| 0, 1 | Tag 0x2954                                                     |
| 2, 3 | Length Variable                                                |
| 4-n  | Value[0-n] Null Terminated ASCII for user name in Request URI. |

**0x2955 SIP Request URI Host Name**

Used to specify the host name in the Request URI. If the host provides the Request URI parameters, it must also provide the “To Header” parameters. (See TLVs 0x2919, 0x291A, 0x291B, 0x291C). The host must also provide the URI user name and port name (See TLVs 0x2954 and 0x2956).

Used in:

0x0033 NPDI Universal ICB in:

*Route Control* message

*Request for Service with Data* message

| Byte | Description                                                    |
|------|----------------------------------------------------------------|
| 0, 1 | Tag 0x2955                                                     |
| 2, 3 | Length Variable                                                |
| 4-n  | Value[0-n] Null Terminated ASCII for host name in Request URI. |

**0x2956 SIP Request URI Port**

Used to specify the port name in the Request URI. If the host provides the Request URI parameters, it must also provide the “To Header” parameters. (See TLVs 0x2919, 0x291A, 0x291B, and 0x291C). The host must also provide the URI host name and user name (See TLVs 0x2954 and 0x2956).

Used in:

*0x0033 NPD Universal ICB in:*

| Byte | Description                     |
|------|---------------------------------|
| 0, 1 | Tag 0x2956                      |
| 2, 3 | Length 0x0004                   |
| 4    | Data[0] MSB Port in Request URI |
|      | Data[1] :                       |
|      | Data[2] :                       |
|      | Data[3] LSB Port in Request URI |

**0x2957 SIP Request URI User Information Qualifier**

Use this TLV to append a user-defined ASCII string to the Request URI user name in outbound SIP calls from the CSP. Specifically, the ASCII string is populated in the user information of the Request-URI header in the outbound SIP INVITE message.

When the CSP is in a SIP/PSTN gateway environment, you can use this TLV to report the terminating trunk group information in a PSTN-to-SIP call.

If the host provides the Request URI parameters, it must also provide the “To Header” parameters. (See TLVs 0x2919, 0x291A, 0x291B, and 0x291C).

Used in:

*0x0033 NPD Universal ICB in:*

*Route Control* message

*Outseize Control* message

| Byte | Description                             |
|------|-----------------------------------------|
| 0, 1 | Tag 0x2957                              |
| 2, 3 | Length Variable                         |
| 4-7  | Value[0-n] Null-terminated ASCII string |

**0x2958 SIP Request URI Parameters**

Use this TLV to receive and send proprietary Request URI Parameters to and from host application. For inbound calls, this TLV carries all of the Request URI parameters received by the SIP stack in the *Request for Service with Data* message to host applications.

To report this TLV to the host, you must program the new Bit 6 in the SIP Message Information Mask TLV (0x027F) used in the *VoIP Protocol Configure* message (0x00EE).

For outbound calls, host application developers can use this TLV in the *Route Control* and *Outseize Control* messages to insert Request URI parameters in SIP INVITE messages.

Used in:

0x0033 NPDI Universal ICB in:

*Request for Service with Data* message

*Route Control* message

*Outseize Control* message

| Byte | Description                             |
|------|-----------------------------------------|
| 0, 1 | Tag 0x2958                              |
| 2, 3 | Length Variable                         |
| 4-n  | Value[0-n] Null-terminated ASCII string |

**0x2959 SIP Remote Party ID**

Used in:

*Request for Service with Data* (0x002D)

| Byte | Description                                                                               |
|------|-------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x2959                                                                                |
| 2, 3 | Length Variable                                                                           |
| 4-7  | Value Contains the value of the Remote Party ID header as a null-terminated ASCII string. |

**0x295A SIP RPID Privacy***Used in:**Request for Service with Data (0x002D)*

| Byte | Description                                                                            |
|------|----------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x295A                                                                             |
| 2, 3 | Length Variable                                                                        |
| 4-7  | Value Contains the value of the RPID Privacy header as a null terminated ASCII string. |

**0x295E SIP Hostname**

This TLV contains the Hostname in the Header Field.

| Byte | Description                          |
|------|--------------------------------------|
| 0, 1 | Tag 0x295E                           |
| 2, 3 | Length Variable                      |
| 4-n  | Value A null-terminated ASCII string |

**0x295F SIP Port Number**

This TLV contains the Port Number in the Header Field.

| Byte | Description    |
|------|----------------|
| 0, 1 | Tag 0x295F     |
| 2, 3 | Length 0x0004  |
| 4-7  | Value Variable |

**0x299A SIP Header Field Container**

For SIP calls, this TLV contains the nested TLVs that in turn contain information regarding SIP Header Fields.

*Used in:*

0x0033 NPDI Universal ICB

This TLV uses the following nested TLVs:

- 0x299B SIP Header Field ID
- 0x299C SIP Header Field

| Byte | Description     |
|------|-----------------|
| 0, 1 | Tag 0x299A      |
| 2, 3 | Length Variable |

**0x299B SIP Header Field ID**

This TLV contains the ID of the Header Field being reported.

Used in:

0x0033 NPD Universal ICB

| Byte | Description                           |
|------|---------------------------------------|
| 0, 1 | Tag 0x299B                            |
| 2,3  | Length 0x0002                         |
| 4,5  | Value[0] Valid value:<br>0x0022 - Via |

**0x299C SIP Header Field**

For SIP calls, this TLV contains the nested TLVs that in turn contain the SIP Header Field Parameters.

Used in:

0x0033 NPD Universal ICB

This TLV uses the following nested TLVs:

- 0x295E SIP Hostname
- 0x295F SIP Port Number

| Byte | Description     |
|------|-----------------|
| 0, 1 | Tag 0x299C      |
| 2, 3 | Length Variable |

**0x29D4 SIP Do Not Close Socket**

Allows an out bound call via TCP to keep its socket. Normally TCP sockets are closed after a period of time after the last message in a transaction is sent. If you include this TLV in a *Route Control* message that causes the use of a TCP socket, the socket will not be closed until explicitly commanded to close by the host with a PPL Event Request.

Used in:

*0x0033 NPDI Universal ICB in:*

*Route Control message*

| Byte | Description                                                                                                |
|------|------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x29D4                                                                                                 |
| 2, 3 | Length 0x0001                                                                                              |
| 4    | Value[0] 0x00 Close socket as if this TLV were not sent<br>0x01 Do not close this socket (persistent mode) |

### **0x29FF Media Local End Point Information**

SIP

For SIP calls, this TLV contains the nested TLVs that in turn contain the entire Session Description Protocol (SDP) in NPDI format. In the *Request for Service* or *PPL Event Indication* messages, this TLV cannot exceed 250 bytes.

Used in: 0x0033 NPDI Universal ICB

RTP

This TLV uses the following nested TLVs that contain the Local End-Point Media Information.

- 0x2A01 Media Per Stream Information
- 0x2A07 Media Port
- 0x2A0E Media Connection Address

| Byte | Description     |
|------|-----------------|
| 0, 1 | Tag 0x29FF      |
| 2, 3 | Length Variable |

### **0x2A00 Media Remote End Point Information**

SIP

For SIP calls, this TLV contains the nested TLVs that in turn contain the entire Session Description Protocol (SDP) in NPDI format.

Used in: 0x0033 NPDI Universal ICB

RTP

This TLV uses the following nested TLVs that contain the Remote End-Point Media Information.

- 0x2A01 Media Per Stream Information
- 0x2A07 Media Port
- 0x2A0E Media Connection Address

| Byte | Description     |
|------|-----------------|
| 0, 1 | Tag 0x2A00      |
| 2, 3 | Length Variable |

### 0x2A01 Media Per Stream Information

#### SIP

For SIP calls, this TLV contains the nested TLVs that in turn contain the media stream in NPDI format.

Used in: 0x0033 NPDI Universal ICB

#### RTP

For Media Streaming over RTP, this TLV is a nested TLV that contains the media stream information. This TLV is nested in the following TLVs in the *Play File Start 0x011B* message:

0x29FF Media Local End Point Information

0x2A00 Media Remote End Point Information

| Byte | Description     |
|------|-----------------|
| 0, 1 | Tag 0x2A01      |
| 2, 3 | Length Variable |

### 0x2A02 Media Per Codec Information

#### SIP

This TLV contains the nested TLVs that in turn contain information about each codec per media stream.

Used in: 0x0033 NPDI Universal ICB

#### RTP

| Byte | Description     |
|------|-----------------|
| 0, 1 | Tag 0x2A02      |
| 2, 3 | Length Variable |

**0x2A03 Media Type**

SIP

This TLV defines the type of media for each media stream.

Used in: 0x0033 NPDI Universal ICB

RTP

| Byte | Description                                                                             |
|------|-----------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x2A03                                                                              |
| 2, 3 | Length 0x0001                                                                           |
| 4    | Value Media Type<br><br>0xFF Invalid<br>0x00 Audio<br>0x01 Video (Requires Call Agent.) |

**0x2A07 Media Port**

This TLV defines the port for each media stream.

SIP

Used in: 0x0033 NPDI Universal ICB

RTP

| Byte | Description            |
|------|------------------------|
| 0, 1 | Tag 0x2A07             |
| 2, 3 | Length 0x0004          |
| 4-7  | Value [0-3] Media Port |

**0x2A08 Media Payload Type**

This TLV carries the actual payload type ID from either the NPDI static payload types or from network signaling data for dynamic payload types.

SIP

**0x2A09 Media Payload Description**

This TLV carries the numerical mapping of a textual payload type string, received for example in the SDP RTPMAP attribute. This TLV is typically present when the Media Payload Type TLV carries a dynamic payload type number.

| 0, 1 | Tag 0x2A0B            |
| 2, 3 | Length 0x0004         |
| 4-7  | Value[0-3] Clock Rate |

**0x2A0E Media Connection Address**

This TLV provides the IP address for each media stream.

Used in:

0x0033 NPDI Universal ICB

| Byte | Description           |
|------|-----------------------|
| 0, 1 | Tag 0x2A0E            |
| 2, 3 | Length 0x0004         |
| 4-7  | Value[0-3] IP Address |

**0x2A13 Media Flow Direction**

This TLV defines the media flow direction.

Used in:

0x0033 NPDI Universal ICB

| Byte | Description                                                                                                                                                                                    |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x2A13                                                                                                                                                                                     |
| 2, 3 | Length 0x0001                                                                                                                                                                                  |

**0x4E21 Message Configuration Valid**

Used in:

*SS7 ISUP Message Format Configure* message

| Byte | Description                                      |
|------|--------------------------------------------------|
| 0, 1 | Tag 0x4E21                                       |
| 2, 3 | Length 0x0001                                    |
| 4    | Value[0]<br>0x00 Invalid<br>0x01 Valid (Default) |

**0x4E22 Message Processing Supported**

The following table defines the format of the Message Configuration Supported TLV:

Used in:

*SS7 ISUP Message Format Configure* message

| Byte | Description                                             |
|------|---------------------------------------------------------|
| 0, 1 | Tag 0x4E22                                              |
| 2, 3 | Length 0x0001                                           |
| 4    | Value[0] 0x00 Not Supported<br>0x01 Supported (Default) |

**0x4E24 Acceptance Rate**

Used in:

0x1E Generic PPL ICB in *PPL Request* message

| Byte | Description                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------|
| 0, 1 | Tag 0x4E24                                                                                                                        |
| 2, 3 | Length 0x0003                                                                                                                     |
| 4    | Value[0] ACL Level<br>0x01 or 0x02                                                                                                |
| 5,6  | Value[1,2] Acceptance Rate - Number of calls per second for this ACL Level.<br><br>MSB - Acceptance Rate<br>LSB - Acceptance Rate |

**0x9041 Protocol Parameters**

Use this TLV to either:

- assign the default standard and network identity

or

- create maps and assign the values for standard and network identity to the maps

Used in:

*NGA Configure* message

| Byte  | Description                                                                                                                                                                |

## Mapping BT IUP Messages to TLV Format

This section defines the TLVs required in a IUP DATA ICB to compose each message. TLVs may appear in any order within the IUP DATA ICB. If a TLV is not included and is required for the underlying PNO-ISC IUP Message a default value will be supplied from the appropriate configuration byte. Therefore, many messages can be generated from the configuration data area by only encoding a message containing the H0H1 TLV, since this uniquely identifies the message to be sent. However, several messages require additional TLVs to uniquely identify the message (for example, ACI and ASUI).

| BT IUP Message                                                          | Valid TLVs                     |

# 5 Response Status Values

## Overview

---

**Purpose** This chapter lists the Response Status Values (RSVs) used in the EXS API for the CSP. These values are in hexadecimal.

## Response Status Values List

| Hex ID      | Name                                                                                                                                 | Description as necessary                                                                                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00 00-00 0F | These values differ depending on the message that returns them. Please refer to the specific message for the response status values. |                                                                                                                                                                                                                                                                                                                                           |
| 00 10       | Positive Acknowledgment (ACK)                                                                                                        | The message was successfully processed, and any required actions were successfully completed.                                                                                                                                                                                                                                             |
| 00 11       | Bad Checksum                                                                                                                         | The message checksum does not match the checksum calculated by the system. An error must exist or a field must be missing.                                                                                                                                                                                                                |
| 00 12       | Invalid Logical Span ID                                                                                                              | A field reserved for a logical span ID contains a number larger than the capacity of the switching matrix.                                                                                                                                                                                                                                |
| 00 13       | Invalid Channel Number                                                                                                               | A field reserved for a channel number is outside the range of 0–30 for E1 or 0–23 for T1. For E1, you can reference channel 30 only if the channel is configured for CCS, with the <i>E1 Span Configure</i> message.                                                                                                                      |

| 00 27 | DSP Not Configured for Requested Function | No DSPs are configured for the function requested by the host (for example, configuration for service).                                                                                                                                                                                                                                                                              |
| 00 28 | DSP Resources Not Available               | No DSP resources are currently available for the requested DSP function. Applies to DSP functions which are not managed as shared resources, for example, <i>Conference Create</i> .                                                                                                                                                                                                 |
| 00 29 | Invalid Conference Output Option          | Conference output option indicated in the <i>Conference Create</i> message is not valid.                                                                                                                                                                                                                                                                                             |
| 00 2A | Invalid Conference ID                     | Conference ID sent by the host is not associated with any conferences previously established through the <i>Conference Create</i> message.                                                                                                                                                                                                                                           |
| 00 2B | <i>Conference Create</i> Failure          | Conference creation failed while the conference was establishing (for example, the MFDSP card was removed).                                                                                                                                                                                                                                                                          |
| 00 2C | Conference Establishing                   | Returned in a <i>Delete Conference</i> , <i>Connect to Conference</i> , or <i>Connect 1-Way to Conference</i> message if the conference associated with the conference ID is in the process of being created.                                                                                                                                                                        |
| 00 2D | Incompatible PCM Encoding for Conference  | Returned in a <i>Connect to Conference</i> and <i>Connect 1-Way to Conference</i> message when the channel encoding format doesn't match that of the conference (for example, A-law encoded channel connected to a $\mu$ -law encoded conference).                                                                                                                                   |
| 00 2E | Conference Size Exceeded                  | Returned in a <i>Connect to Conference</i> message when the conference size has been exceeded.                                                                                                                                                                                                                                                                                       |
| 00 2F | Maximum Broadcast Number Exceeded         | Returned in a <i>Connect 1-Way</i> or <i>Connect 1-Way to Conference</i> message when the number of 1-Way broadcasts exceeds the maximum allowed.                                                                                                                                                                                                                                    |
| 00 30 | DSP Resource Already Allocated            | Returned in a <i>Collect Digit String</i> or <i>DSP Service Request</i> message if digit collection is already active on the specified channel.                                                                                                                                                                                                                                      |
| 00 31 | Channel Violation                         | Returned if an Matrix Controller 1000 Series 3 card is being used in a system with more than 1,024 channels.                                                                                                                                                                                                                                                                         |
| 00 32 | Channels A and B Already Connected        | A connect request has been sent for two channels which are already connected.                                                                                                                                                                                                                                                                                                        |
| 00 33 | SS7 Configuration Error                   | Possible scenarios regarding virtual spans:<br>1. Configuring virtual CICs on remote nodes using an SS7 PQ card in the server node.<br>2. Configuring virtual CICs on a virtual VOCC card (type 0x80) using either an SS7 PQ card or an HP card.<br>3. Configuring virtual CICs beyond five virtual T-ONE cards or four virtual E-ONE cards on the server node using an SS7 PQ card. |
| 00 34 | Ring Timeslot Inaccessible                | Remote timeslot is not accessible from this node. Check CSP hardware.                                                                                                                                                                                                                                                                                                                |
| 00 35 | Invalid Logical Ring ID                   |                                                                                                                                                                                                                                                                                                                                                                                      |

| 00 B3 | System Table in Use                    | System software is using the table you are trying to modify/create. Please wait a few seconds and try again.                                                                                                                           |
| 00 B4 | Line Card Response To Matrix Timeout   | The matrix timed-out waiting for a response from a line card. Check configuration for channel ranges that span more than two cards.                                                                                                    |
| 00 B5 | CPA Member Exceeds Maximum For Class   | The maximum number of call progress analysis patterns which can be included in a class has been reached.                                                                                                                               |
| 00 B6 | CPA Pattern Exceeds Maximum            | The maximum amount of call progress analysis patterns supported by the system has been reached.                                                                                                                                        |
| 00 B7 | CPA Tone Group Exceeds Maximum         | The maximum amount of call progress analysis tone groups supported by the system has been reached.                                                                                                                                     |
| 00 B8 | Invalid Pattern ID                     | An invalid pattern ID has been specified for call progress analysis.                                                                                                                                                                   |
| 00 B9 | Invalid Interval Descriptor Count      | An invalid interval descriptor count has been specified for call progress analysis.                                                                                                                                                    |
| 00 BA | CPA Classes Exceeds Maximum            | The maximum amount of call progress analysis classes supported by the system has been reached.                                                                                                                                         |
| 00 BB | Invalid CPA Class                      | An invalid call progress analysis class was specified in a configuration message.                                                                                                                                                      |
| 00 BC | Invalid Data Found at Byte N           | The message became invalid because of data found at byte offset N. See the LSB of the <i>Status</i> field of the message for the byte offset where data became invalid.                                                                |
| 00 BD | Invalid Table Type                     | The table type specified is invalid.                                                                                                                                                                                                   |
| 00 BE | Invalid Table ID                       | The table ID specified is invalid.                                                                                                                                                                                                     |
| 00 BF | ISDN Response Wait Timeout             | ISDN-initiated message timed-out; waiting for a response from the network (for example, Register with no Release Complete).                                                                                                            |
| 00 C0 | Action Denied                          | Action request denied.                                                                                                                                                                                                                 |
| 00 C1 | Action Rejected                        | Action request rejected.                                                                                                                                                                                                               |
| 00 C2 | Slot Assigned As Standby               | The slot number is assigned as a standby slot.                                                                                                                                                                                         |
| 00 C3 | Slot Not Assigned As Standby           | The slot number is not assigned as a standby slot.                                                                                                                                                                                     |
| 00 C4 | Standby I/O Relay State Mismatch       | The states of the relays of the I/O cards specified do not match (relays on one are enabled; relays on the other are disabled).                                                                                                        |
| 00 C5 | Incompatible Line Card Types           | The line cards specified are not compatible.                                                                                                                                                                                           |
| 00 C6 | Redundant I/O Cards Not Present        | Redundant I/O cards are not present in one or more of the slots specified.                                                                                                                                                             |
| 00 C7 | Line Card Switchover Already Completed | The <i>Line Card Switchover</i> requested has already been completed.                                                                                                                                                                  |
| 00 C8 | Invalid SIMM Type                      | Trying to perform VRAS functions on a non-VRAS SIMM.                                                                                                                                                                                   |
| 00 C9 | Invalid Recorded Announcement ID       | The recorded announcement ID is not in the allowable range or the host has requested a recorded announcement ID that does not exist in the system.<br><u>Allowed Range</u><br>MFDSP/DSP-ONE: 0 - 4,095<br>DSP Series 2: Not Applicable |
| 00 CA | Recorded Announcement Already Exists   | The host has attempted to download an announcement using a recorded announcement ID that is already stored in the system.                                                                                                              |
| 00 CB | Insufficient Memory on VRAS SIMM       | Not enough memory to store the specified recorded announcement.                                                                                                                                                                        |

|       |                                                          |                                                                                                                                                                                       |
|-------|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00 CC | Maximum Recorded Announcement Limit Reached on VRAS SIMM | The host has attempted to download more than the maximum allowed recorded announcements to a particular VRAS SIMM.<br>MFDSP - 300<br>DSP-ONE - 2,048<br>DSP Series 2 - Does Not Apply |
| 00 CD | Invalid IE Length                                        | The host has sent an information element (IE) in an ICB with an incorrect length.                                                                                                     |
| 00 CE | Invalid IE Count                                         | The host has sent an ICB with an incorrect <i>IE Count</i> value.                                                                                                                     |
| 00 CF | Invalid Component Type                                   | The host has sent an ICB with an incorrect component type.                                                                                                                            |
| 00 D0 | ISDN D Channel Switchover Timed Out                      | The D channel switchover could not be completed due to timer expiration.                                                                                                              |
| 00 D1 | Invalid ISDN Connection Endpoint Identifier              | A valid Connection Endpoint Identifier could not be found for the addressed D channel.                                                                                                |
| 00 D2 | Invalid AIB                                              | The address information block (AIB) is not in the proper format, or it addresses an invalid PPL state machine or channel.                                                             |
| 00 D3 | Invalid Protocol ID                                      | A protocol ID specified in a PPL message is invalid.                                                                                                                                  |
| 00 D5 | Channel Already In Service                               | Applies to ISDN and SS7 only. Indicates that you attempted to either assign or de-assign a protocol to a channel that is in service.                                                  |
| 00 D6 | Invalid Command For Trunk Front End                      | An invalid command was sent from the host for a trunk front end.                                                                                                                      |
| 00 D7 | End Of PPL Audit Data                                    | The end of the PPL auditing data has been reached. There are no more PPL auditing blocks in the PPL auditing logs.                                                                    |
| 00 D8 | Invalid SS7 Signaling Stack ID (0–3)                     | A signaling stack was specified that either:<br>Was greater than the allowed values (0–3), or<br>Did not match the signaling stack for the primary resource                           |
| 00 D9 | SS7 Signaling Stack Already Configured                   | An attempt was made to configure an SS7 signaling stack that is already configured.                                                                                                   |
| 00 DA | Invalid SS7 Module Count                                 | An attempt was made to configure an SS7 signaling stack with an invalid number of modules. The module count must be 3.                                                                |
| 00 DB | Duplicated SS7 Module                                    | An SS7 signaling stack configuration attempt specified the same SS7 model more than once.                                                                                             |
| 00 DC | Unsupported SS7 Module Variant                           | An SS7 signaling stack configuration attempt specified an unsupported SS7 module variant.                                                                                             |
| 00 DE | Invalid SS7 Module Type                                  | An SS7 signaling stack configuration attempt specified an invalid SS7 module type.                                                                                                    |
| 00 DF | Invalid SS7 Signaling Stack Configuration                | An SS7 signaling stack configuration attempt could not be interpreted correctly.                                                                                                      |
| 00 E0 | SS7 Signaling Stack Not Configured                       | An SS7 signaling stack configuration attempt specified a signaling stack ID that is not configured.                                                                                   |
| 00 E1 | Invalid SS7 Signaling Link ID                            | An invalid SS7 signaling link ID was specified that was either:<br>Too large for the SS7 card model, or<br>An attempt was made to de-configure a link that is not configured.         |
| 00 E2 | Invalid SS7 Signaling Link Set ID                        | An invalid SS7 signaling link set ID was specified. Valid Link Set IDs are 0 to 35.                                                                                                   |
| 00 E3 | SS7 Signaling Link Set Not Configured                    | An SS7 configuration attempt specified a signaling link set that is not configured.                                                                                                   |
| 00 E4 | SS7 Signaling Link Already Configured                    | An SS7 configuration attempt expected the specified SS7 signaling link either:<br>Was not configured, or<br>Did not have configured SS7 signaling links                               |
| 00 E5 | Invalid SS7 SLC                                          | An SS7 configuration attempt specified an invalid SLC. Valid SLC codes are 0 to 15.                                                                                                   |

**MSB 0x18 - Invalid B Channel State**

The LSB indicates the current call state.

If the value is 0x1850 or above, it indicates the Layer 3 State. The Layer 3 state values depend on the signaling protocol. See the appropriate \*.ppl file (CD ROM only) for Layer 3 state values, or contact Cantata technical support.

If the value is lower than 0x1850, it indicates the Layer 4 State. The Layer 4 states are defined below. Some values are not backward-compatible with System Software versions earlier than 5.3.

| 55 03 | PPL Event Request: Incorrect or Missing Mandatory TCAP Parameter            |
|       | SCCPTCAP Configure: Subsystem Not Configured                                |
| 55 04 | PPL Event Request: Incorrect or Missing Mandatory SCCP Parameter            |
|       | SCCPTCAP Configure: Subsystem Allowed                                       |
| 55 05 | PPL Event Request: Invalid Primitive (Primitive Not Supported)              |
|       | SCCPTCAP Configure: Subsystem Not Allowed                                   |
| 55 06 | PPL Event Request: Instance does not Exist                                  |
|       | SCCPTCAP Configure: Invalid Option                                          |
| 55 07 | PPL Event Request: Primitive Not Expected at this Time                      |
|       | SCCPTCAP Configure: Exceeds minimum number of hosts for a Subsystem         |
| 55 08 | PPL Event Request: Mandatory Component Missing                              |
|       | SCCPTCAP Configure: Invalid Parameter                                       |
| 55 09 | PPL Event Request: Resource Limitation                                      |
|       | SCCPTCAP Configure: Invalid Parameter Length                                |
| 55 0A | PPL Event Request: SSN is not Configured or not Active                      |
|       | SCCPTCAP Configure: Parameter Configured                                    |
| 55 0B | PPL Event Request: Maximum Length of TCAP Components for a Message Exceeded |
|       | SCCPTCAP Configure: Parameter Not Configured                                |
| 55 0C | Invalid SCCP Upper Layer                                                    |
| 55 0D | Maximum Active Subsystems Exceeded                                          |
| 55 0E | DPC Not Configured                                                          |

# 6 PPL Component Information

## Overview

---

**Purpose** This chapter contains information regarding PPL Components for PPL software development on the CSP.

## PPL Component IDs

---

This section lists the PPL Component IDs used in PPL software development for the CSP. The component IDs are listed by protocol.

**Important!** All the PPL components listed in this section support the extended PPL table type except for those showing otherwise.

|                                                         |                                                                                                       |  |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------|--|
| <b>Component Modification</b>                           | Components that are released for modification using the PPL Composer are marked with an asterisk (*). |  |
| <b>T1</b>                                               | 0x0003 T1 PPL Component* (Supports basic PPL table type only)                                         |  |
| <b>E1</b>                                               | 0x0001 E1 PPL Component* (Supports basic PPL table type only)                                         |  |
| <b>Layer 4/Layer 5 Call Control<br/>PPL Information</b> | 0x0061 Channel Management*                                                                            |  |
|                                                         | 0x0062 Call Management*                                                                               |  |
|                                                         | 0x0063 Physical Connection Management*                                                                |  |
|                                                         | 0x0064 Router*                                                                                        |  |
|                                                         | 0x0084 Interworking                                                                                   |  |
|                                                         | 0x0086 MCC Group                                                                                      |  |
|                                                         | 0x0087 MCC Channel                                                                                    |  |
| <b>SS7</b>                                              | <b>L3P</b>                                                                                            |  |
|                                                         | 0x000F L3P CIC (CIC Call Control)*                                                                    |  |
|                                                         | 0x0010 L3P Link (Link Management)*                                                                    |  |

**ISUP**

0x0012 ISUP CPC (Call Processing Control) \*

0x0013 ISUP SPRC (Signaling Procedure Control)\*

0x0014 ISUP CCI (Continuity Check Incoming)

0x0015 ISUP CRI (Continuity Recheck Incoming)

0x0016 ISUP BLS (Blocking/Unblocking Signal Sending)

0x0017 ISUP BLR (Blocking/Unblocking Signal Reception)

0x0018 ISUP CRS (Circuit Reset Sending)

0x0019 ISUP CRR (Circuit Reset Reception)

0x001A ISUP UCIC (Unequipped CIC Reception)

0x001B ISUP CGRS (Circuit Group Reset Sending)

0x001C ISUP CGRR (Circuit Group Reset Reception)

0x001D ISUP GBUS (Circuit Group Blocking/Unblocking Sending)

0x001E ISUP GBUR (Circuit Group Blocking/Unblocking Reception)

0x001F ISUP HGBR (Hardware Oriented Circuit Group Blocking/  
Unblocking Reception)

0x0042 ISUP HLB (Hardware Failure Oriented Locally Blocking State)

0x0043 ISUP HRB (Hardware Failure Oriented Remotely Blocking)

0x0044 ISUP CRCR (Continuity Recheck Reception)

0x0045 ISUP MGBS (Maintenance Oriented Circuit Group Blocking/  
Unblocking Sending)

0x0046 ISUP MGBR (Maintenance Oriented Circuit Group Blocking/  
Unblocking Reception)

0x0047 ISUP HGBS (Hardware Oriented Circuit Group Blocking/  
Unblocking Sending)

0x0076 ISUP CQS(Circuit Query Sending)

0x0077 ISUP CQR (Circuit Query Receiving)

0x0078 ISUP CVS (Circuit Validation Sending)

0x0079 ISUP CVR (Circuit Validation Receiving)

0x0080 ISUP CCO (Continuity Check Outgoing)

0x0081 ISUP CRCS (Continuity Check Resending)

0x0082 ISUP DCO (Demand Continuity Outgoing)

0x0083 ISUP CRO (Continuity Recheck Outgoing)

0x0085 ISUP SSC (Simple Segmentation Control)

0x00A8 ISUP ACC (Automatic Congestion Control)

**TUP**

0x0011 L3P TUP (Telephone User Part)\*  
0x0052 TUP CPC (Call Processing Control)\*  
0x0053 TUP SPRC (Signaling Procedure Control)\*  
0x0054 TUP BLR (Blocking/Unblocking Signal Reception)  
0x0055 TUP BLS (Blocking/Unblocking Signal Sending)  
0x0057 TUP CRI (Continuity Recheck Incoming)  
0x0058 TUP CRS (Circuit Reset Sending)  
0x0059 TUP CGRR (Circuit Group Reset Reception)  
0x005A TUP CGRS (Circuit Group Reset Sending)  
0x005B TUP MBUS (Maintenance Block/Unblock Sending)  
0x005C TUP MBUR (Maintenance Block/Unblock Receiving)  
0x005D TUP HBUS (Hardware Block/Unblock Sending)  
0x005E TUP HBUR (Hardware Block/Unblock Receiving)  
0x005F TUP SBUS (Software Block/Unblock Sending)  
0x0060 TUP SBUR (Software Block/Unblock Receiving)

**SSUTR2**

0x0011 L3P SSUTR2  
0x0052 SSUTR2 CPC (Call Processing Control)  
0x0053 SSUTR2 SPRC (Signaling Procedure Control)  
0x0054 SSUTR2 BLR (Blocking/Unblocking Signal Reception)  
0x0055 SSUTR2 BLS (Blocking/Unblocking Signal Sending)  
0x0057 SSUTR2 CRI (Continuity Recheck Incoming)  
0x0058 SSUTR2 CRS (Circuit Reset Sending)  
0x007C SSUTR2 CRO (Continuity Recheck Outgoing)

**BT IUP**

0x0011 L3P BT IUP (Interconnect User Part)  
0x0052 BT IUP CPC (Call Processing Control)  
0x0053 BT IUP SPRC (Signaling Procedure Control)

**MTP3**

0x002B MTP3 HMDT (Message Distribution)  
0x002C MTP3 HMRT (Message Routing)  
0x002D MTP3 LLSC (Link Set Control)  
0x002E MTP3 LSAC (Signaling Link Activity Control)  
0x0032 MTP3 RCAT (Signaling Route Set Congestion Test Control)  
0x0033 MTP3 RSRT (Signaling Route Set Test Control)  
0x0034 MTP3 RTAC (Transfer Allowed Control)  
0x0035 MTP3 RTCC (Transfer Controlled Control)  
0x0036 MTP3 RTPC (Transfer Prohibited Control)  
0x0037 MTP3 RTRC (Transfer Restricted Control)  
0x0038 MTP3 TCBC (Changeback Control)  
0x0039 MTP3 TCOC (Changeover Control)  
0x003A MTP3 TCRC (Controlled Rerouting Control)  
0x003C MTP3 TLAC (Link Availability Control)  
0x003D MTP3 TPRC (Signaling Point Restart Control)  
0x003E MTP3 TRCC (Signaling Route Set Congestion Control)  
0x003F MTP3 TSFC (Signaling Traffic Flow Control)  
0x0040 MTP3 TSRC (Signaling Route Control)  
0x0041 MTP3 SLTC (Signaling Link Test Control)

**MTP2**

0x0020 MTP2 AERM (Alignment Error Rate Monitor)  
0x0021 MTP2 CC (Congestion Control)  
0x0022 MTP2 IAC (Initial Alignment Control)  
0x0023 MTP2 LSC (Link State Control)  
0x0024 MTP2 RC (Reception Control)  
0x0025 MTP2 SUERM (Signal Unit Error Rate Monitor)  
0x0026 MTP2 TXC (Transmission Control)

**SCCP**

0x0065 SCLC (SCCP Connectionless Control)

0x0066 SCRC (SCCP Routing Control)

0x0067 SUSI (SCCP User Interface)

0x0068 SPPC (Signaling Point Prohibited Control)

# PPL Component Addressing

---

**Overview** This section lists the PPL Components and the associated AIBs used for PPL messages.

**Guidelines** The following are guidelines for the information in the tables later in this section.

- PPL timer and configuration bytes are stored on a *per channel* basis.
- The *PPL Transmit Signal Configure* message (0xD2) is applies to the E1 and T1 protocols.

The tables later in this section show the AIBs used to address the various PPL components in these PPL-related API messages listed below:

- *PPL Assign* (0xD1)
- *PPL Audit Configure* (0xDC)
- *PPL Audit Query* (0xDD)
- *PPL Configure* (0xD7)
- *PPL Data Query* (0xDE)
- *PPL Event Indication* (0x43)
- *PPL Event Request* (0x44)
- *PPL Timer Configure* (0xCF)

The *PPL Transmit Signal Configure* message is not included in the tables because it uses the Channel address AIB only.

For span/channel addressed state machines, the following messages can use either a single entity or range address method:

- *PPL Assign* (0xD1)
- *PPL Configure* (0xD7)
- *PPL Timer Configure* (0xCF)
- *PPL Transmit Signal Configure* (0xD2)

For span/channel addressed state machines, the following messages use a single entity address method only:

- *PPL Audit Query* (0xDD)
- *PPL Data Query* (0xDE)

- *PPL Event Indication* (0x43)
- *PPL Event Request* (0x44)

For information on AIB formats, refer to the *Address Elements* chapter.

## PPL Events

The *PPL Event Indication* and *PPL Event Request* messages are used to send and receive additional call processing data about the call.

### *PPL Event Request*

This message is initiated by the host, and sends an external event directly to the specified PPL component.

### *PPL Event Indication*

This message enables the PPL component on the CSP to report external events to the host application.

The *PPL Event Request* and *PPL Event Indication* messages must include the PPL component and event. They can include optional data in an ICB.

ICB subtype values can include Layer 3 (ISDN, SS7, SIP, or H.323) parameters. Refer to the *Information Control Blocks* chapter.

## E1/T1

| Comp. ID          | Comp. Name | PPL Assign     | PPL Audit Config. | PPL Audit Query | PPL Config. | PPL Data Query | PPL Event Request | PPL Timer Config. |
|-------------------|------------|----------------|-------------------|-----------------|-------------|----------------|-------------------|-------------------|
| 0x0001/<br>0x0003 | E1/T1      | Channel (0x0D) |                   |                 |             |                |                   |                   |

# 7 Timers and Filters

## Overview

---

**Purpose** This chapter lists the Timers and Filters used in the EXS API for the CSP.

The CSP expects timers in API messages to be configured in 10-millisecond units, Most Significant Byte (MSB) first and Least Significant Byte (LSB) second.

To determine a timer of 10 seconds, you must convert the time to millisecond units (s = seconds, ms = milliseconds):

$10\text{ s} = 10,000\text{ ms} = 1,000\text{ 10-ms units}$

$1,000 = 3\text{E8}$  in hexadecimal, which is expressed as 0x03, 0xE8.

You can determine timers using the conversion chart in the following section.

## Timer Conversion Table

---

Use the table below to convert times into the format explained above.

The length of your timer is listed in the *Time* column and the timer's hexadecimal equivalent is listed in the *MSB* and *LSB* columns.

| <b>Time</b> | <b>MSB</b> | <b>LSB</b> |
|-------------|------------|------------|
| 50 ms       | 0x00       | 0x05       |
| 100 ms      | 0x00       | 0x0A       |
| 150 ms      | 0x00       | 0x0F       |
| 200 ms      | 0x00       | 0x14       |
| 250 ms      | 0x00       | 0x19       |
| 300 ms      | 0x00       | 0x1E       |
| 350 ms      | 0x00       | 0x23       |
| 400 ms      | 0x00       | 0x28       |
| 450 ms      | 0x00       | 0x2D       |
| 500 ms      | 0x00       | 0x32       |
| 550 ms      | 0x00       | 0x37       |
| 600 ms      | 0x00       | 0x3C       |
| 650 ms      | 0x00       | 0x41       |
| 700 ms      | 0x00       | 0x46       |
| 750 ms      | 0x00       | 0x4B       |
| 800 ms      | 0x00       | 0x50       |
| 850 ms      | 0x00       | 0x55       |
| 900 ms      | 0x00       | 0x5A       |
| 950 ms      | 0x00       | 0x5F       |
| 1050 ms     | 0x00       | 0x69       |
| 1100 ms     | 0x00       | 0x6E       |
| 1150 ms     | 0x00       | 0x73       |
| 1200 ms     | 0x00       | 0x78       |

| <b>Time</b> | <b>MSB</b> | <b>LSB</b> |
|-------------|------------|------------|
| 1250 ms     | 0x00       | 0x7D       |
| 1300 ms     | 0x00       | 0x82       |
| 1350 ms     | 0x00       | 0x87       |
| 1400 ms     | 0x00       | 0x8C       |
| 1450 ms     | 0x00       | 0x91       |
| 1500 ms     | 0x00       | 0x96       |
| 1550 ms     | 0x00       | 0x9B       |
| 1600 ms     | 0x00       | 0xA0       |

## T1 Filters

---

The *Filter/Timer Configure* message modifies approximately 100 combined timers and filters. There are approximately 14 signal scanning filters, 63 signal scanning timers, and 36 transmit signal timers for T1 trunk types.

Filter values are in 10 millisecond decimal units. If there is no value in a field, the filter does not apply.

### **Signaling Scanning Filters**

Signal Scanning Filters (table below) define the duration that an expected signaling condition is expected to be valid before it is declared to have occurred.

| ID   | PPL Timer No. | Signal Scanning Filter          | E&M | FXO LS | FXS LS | FXO GS | FXS GS |
|------|---------------|---------------------------------|-----|--------|--------|--------|--------|
| 0x01 | 0x01          | Preseize                        | 10  |        |        | 10     |        |
| 0x02 | 0x02          | Inseize                         | 15  | 600    | 20     | 600    | 100    |

**Signaling Scanning Timers** Signal Scanning Timers (table below) define the minimum and maximum acceptable durations for signaling condition to exist from the point they are declared valid.

Timer values are in 10 millisecond decimal units. If there is no value in a field, the timer does not apply.

| ID   | PPL<br>Timer<br>No. | Signal Scanning Timer                 | E&M    | FXO<br>LS | FXS<br>LS | FXO<br>GS | FXS<br>GS |

**Important!** \* To configure the DTMF timers for H.323 use *PPL Timer Configure 0x00CF* and then refer to the *API Developers Guide: IP*, H.323 Chapter.

**Transmit Signaling Timers**

Transmit Signaling Timers (table below) define the durations used when the system is generating signaling or tones. With the T-ONE card, timer values can be modified using either the PPL Timer Configure message

Timer values are in 10 millisecond decimal units. If there is no value in a field, the timer does not apply.

| ID   | PPL Timer No. | Transmit Signaling Timer      | E&M   | FXO LS | FXS LS | FXO GS | FXS GS |

## E1 Timers

---

The table below shows the timers used with the E1 component (0x01).

| Timer ID | Description: (State Used); Timer Description                                                           | Default Value<br>(10 ms) |
|----------|--------------------------------------------------------------------------------------------------------|--------------------------|
| 1        | (S19) Incoming Layer 4 busy out Acknowledge wait                                                       | 400                      |
| 2        | (S2) Incoming Stage 1 FWD digit receive wait                                                           | 2000                     |
| 3        | (S3) Incoming Stage 2 FWD digit receive wait                                                           | 2000                     |
| 4        | (S4) Incoming Stage 3 FWD digit receive wait                                                           | 2000                     |
| 5        | (S5) Incoming Stage 4 FWD digit receive wait                                                           | 2000                     |
| 6        | (S13) Layer 4 Connect wait                                                                             | 24,000                   |
| 7        | (S14) Layer 4 wait                                                                                     | 400                      |
| 8        | (S21) Clear Forward (idle line signaling) wait                                                         | 1500                     |
| 9        | (S3) Incoming Stage 2 Initial FWD digit receive wait                                                   | 2000                     |
| 10       | (S2) Incoming Stage 1 Initial FWD digit receive wait                                                   | 2000                     |
| 11       | (S5) Incoming Stage 4 Initial FWD digit receive wait                                                   | 2000                     |
| 12       | (S4) Incoming Stage 3 Initial FWD digit receive wait                                                   | 2000                     |
| 13       | (S15) Layer 3 Circuit Release wait                                                                     | 10                       |
| 14       | (S18) Layer 3 Circuit Release wait                                                                     | 10                       |
| 15       | (S6) Host Control Wait                                                                                 | 6000                     |
| 16       | (S13) Layer 3 Connect wait                                                                             | 24000                    |
| 17       | (S29) Seize Acknowledge wait                                                                           | 400                      |
| 18       | (S31) Time to wait before transmitting idle signal after detecting glare                               | 10                       |
| 19       | (S32) Time to wait before looking for idle signal after transmitting idle signal after detecting glare | 10                       |
| 20       | (S39) Outgoing Stage 1 BWD R2 signal wait                                                              | 1500                     |
| 21       | (S39) Outgoing Stage 1 Initial BWD R2 signal wait                                                      | 1500                     |
| 22       | (S41) Outgoing Stage 2 BWD R2 signal wait                                                              | 1500                     |
| 23       | (S41) Outgoing Stage 2 Initial BWD R2 signal wait                                                      | 1500                     |

| Timer ID | Description: (State Used); Timer Description                                                                                   | Default Value<br>(10 ms) |
|----------|--------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| 24       | (S43) Outgoing Stage 3 BWD R2 signal wait                                                                                      | 1500                     |
| 25       | (S43) Outgoing Stage 3 Initial BWD R2 signal wait                                                                              | 1500                     |
| 26       | (S45) Outgoing Stage 4 BWD R2 signal wait                                                                                      | 1500                     |
| 27       | (S45) Outgoing Stage 4 Initial BWD R2 signal wait                                                                              | 1500                     |
| 28       | (S46) Outgoing wait for answer                                                                                                 | 24000                    |
| 29       | (S48) Outgoing Layer 4 Clear wait                                                                                              | 400                      |
| 30       | (S49) Outgoing idle line signal wait                                                                                           | 12000                    |
| 31       | (S50) Outgoing idle line signal wait after glare detected                                                                      | 12000                    |
| 32       | (S24) Host Control wait                                                                                                        | 24000                    |
| 33       | (S33) Time to wait for Clear Forward after glare detected                                                                      | 1000                     |
| 34       | Receive line signaling filter                                                                                                  | 4                        |
| 36       | (S6, S24) Incoming BWD R2 Cycle Complete Event wait                                                                            | 400                      |
| 38       | (S10) Time to wait for idle line signaling after invalid line signal detected while receiving FWD R2 digits                    | 2000                     |
| 39       | (S22) Layer 3 Clear Forward wait                                                                                               | 300                      |
| 40       | (S39) Outgoing Stage 1 BWD A signal wait after sending all of Stage 1 FWD digits                                               | 2000                     |
| 41       | (S2, S3, S4, S5) FWD R2 digits receive wait when String Collection Data field in Impulsing Parameters Configure is set to 0xFF | 20                       |
| 43       | R2 Cycle Complete Event wait                                                                                                   | 200                      |
| 45       | (S43) Time to wait for next BWD R2 signal when stage 3 digits have been outpulsed                                              | 2000                     |
